Modern and Historic Views of the World’s Newest and Oldest Global Power

中华全书

跨越历史和现代，审视最新和最古老的全球大国

VOLUME 1

Berkshire Publishing Group
Great Barrington, Massachusetts
Berkshire’s Commitment to Doing Business Sustainably

One of the questions we at Berkshire Publishing constantly ask ourselves is how we can run our business in a way that will help preserve and even restore the planet. As a book publisher, especially one with the ten-volume *Encyclopedia of Sustainability* on our list (see http://www.thesustainabilityproject.com), choosing a “green” print house like Thomson-Shore is an obvious first step. The second is requesting an Eco-Audit sponsored by the Green Press Initiative, a nonprofit organization with a mission to help those in the publishing industry conserve natural resources.

The carbon footprint of publishing is not caused just by printing books on paper—the supply chain and shipping method by which the books get to the customer, for instance, make a substantial contribution to it. But of all of the ways to use paper, producing books is one of the smartest—because books last. Producing works with a long shelf life, which is a matter of both the paper we print on and the words on the page, is an important sustainability concept Berkshire is proud to believe in and practice.

Of course all the work it takes to get a book into print has an environmental impact, including the virtually paperless editorial processes that many sustainability-savvy publishers (Berkshire included) have been gradually adopting. Although many believe that the trend to switch more and more to the electronic world is a planet-friendly move, reading and publishing online are not a carbon-free activities. Turn to the *Encyclopedia of Sustainability* and http://www.thesustainabilityproject.com for details, and for information about Berkshire’s *China Green* publications.

North River Press is committed to preserving ancient forests and natural resources. We elected to print *The Goal* on 50% postconsumer recycled paper, processed chlorine free. As a result, for this printing, we have saved:

- 145 trees (40' tall, 6-8' around)
- 42,315 gallons of water
- 24,784 kilowatt hours of electricity
- 363 pounds of pollution

North River Press made this paper choice because our printer, Thomson-Shore, Inc., is a member of Green Press Initiative, a nonprofit program dedicated to supporting authors, publishers, and suppliers in their efforts to reduce their use of fiber obtained from endangered forests.

© 2009 by Berkshire Publishing Group LLC
As I sat down in early March 2009 to write an introduction to the Encyclopedia of China—the first edition of the first major work of its kind to be published in English—the world was facing unprecedented challenges. Around the globe, nations and their citizens were asking how we could rebuild broken economies, preserve evaporating and depleted natural resources, stabilize political upheavals, and protect human rights. Not since World War II had diplomatic relations between nations been so crucial to our common future. In a stroke of synchronicity, it was also in March 2009 that two nations—a relatively young nation that had established its power in modern times, and an ancient nation reemerging and regaining status as a player in international affairs—were celebrating the thirtieth anniversary of the “normalization” of their diplomatic relations, as well as meeting to discuss climate change cooperation and strategies for global economic recovery.

The three decades during which friendship had developed between the United States and China (not always in forward motion, and not without tense moments) had been preceded by a more difficult thirty-year period, beginning in 1949 with the founding of the Communist Party–led People’s Republic of China. What lies ahead in the next thirty years? We don’t know. But we do agree—statesmen and citizens, teachers and students—that Americans, Europeans, and Westerners in general urgently need to know more about China. We need to look past our stereotypical (and often uninformed or lingering) perspectives—which have indeed wavered back and forth for the last three hundred years—and see China not as a threat but as a partner in building a better future. With this certainty, Berkshire Publishing Group conceived, produced, and now publishes the five-volume Encyclopedia of China.

About the Berkshire Encyclopedia of China

As the first multi-volume, multi-authored Encyclopedia of China to be published outside China itself, Berkshire’s 800-entry, five-volume set offers authoritative articles from well-known Chinese and Western scholars. We at Berkshire, committed to providing truly global perspectives that will empower twenty-first-century students, compiled the encyclopedia with strict guidelines about balance and objectivity. We felt strongly that the Encyclopedia of China should be an invaluable reference tool for general China studies, but that it be relevant outside the
classroom and for students planning careers in China-related business, communications and technology, and public service. We wanted its design and content to appeal to global citizens as well as to leaders in business and government. Students and professionals who need to improve or expand their knowledge of all things Chinese will find articles on arts, belief systems, business, communications, cuisines, demographics, education, law and politics, leadership, minority groups, natural disasters, natural resources, regional and international relations, social welfare, technology, and the changing roles of women.

Outside these categories we provide broad thematic essays that serve as anchors or touchstones for the work as a whole; on the other hand we recognize the need for short entries about people, events, concepts, and material goods—topics that add nuance to the nature of life in China. There are articles on important organizations and companies, as well as on sports, festivals, and aspects of popular culture. And while the encyclopedia brings readers right up to the present—with 2008 Olympic results, information on blogging, Internet use, human rights, and even updates about events such as the military confrontation in the South China Sea that occurred as we prepared to go to press—the Encyclopedia of China looks to the future with articles on renewable energy and the 2010 World’s Fair in Shanghai.

To comprehend China’s spectacular growth in recent decades—a phenomenon proudly broadcast to the world when Beijing hosted the 2008 Olympic Games—it is essential to understand and appreciate the history and culture of China, one of the world’s great civilizations. Accordingly, the Berkshire Encyclopedia of China offers numerous articles about China’s history, beginning five thousand years ago and even further into the past. We explore China’s place in the broad sweep of human history with a comprehensive article on “China in World History” by William H. McNeill, the eminent scholar who led the editorial board of the Berkshire Encyclopedia of World History, published in 2004, and who is now overseeing work on its second edition. Another long entry, “Confucianism—Revival” by Daniel A. Bell, examines how contemporary Chinese are reconnecting with one of the country’s most important ancient traditions, in a search for new inspiration and a philosophy to guide everyday life. This article also connects Berkshire past to present, as I met the author in Hong Kong in 2002 on one of my first trips to Asia. We had been introduced in the course of another project, the Encyclopedia of Community, my own area of research, published by Sage in 2004. Bell has since moved to mainland China and is the first Western scholar to take a regular post in political theory at a leading Chinese university, Tsinghua. We are delighted to include his work here, as he does represent an important bridge between China and the West, and is creating a path for others, in China and outside it.

Contributing authors come from many scholarly disciplines. They include political scientists, sociologists, economists, anthropologists, geographers, historians, scientists, artists, educators, and specialists in other fields. They are based at major U.S., European, and Australian universities, and at specialist research centers including the China Policy Center at the University of Nottingham, the Worldwatch Institute, and the Wilson Center. Thanks to cooperation with and contributions from many Chinese scholars based in China, and Chinese scholars who divide their lives between Western universities and China, the encyclopedia is also the first major work to cover China from the Chinese point of view. In our editing, we have strived to let these perspectives remain clear.

During the three-year process of creating the Berkshire Encyclopedia of China—a project many people thought couldn’t be done—Joseph Needham’s breathtaking series Science and Civilisation in China remained for us a touchstone of sinology itself. It inspired us to present, as Needham did, little-known aspects of Chinese knowledge and innovation, and to go beyond the traditional teaching of Chinese history and literature to look at practical contributions—though in our case, we looked at the full range of human culture and industry.

In the spirit of both scholarship and global cooperation, we encourage readers as well as our current roster of 296 authors, to review the content of this work critically and creatively. We welcome observations, corrections, and additions, and will be adding to this work—which could, quite easily, have been twice the length. We have begun compiling material for the second edition of this encyclopedia, and have started to work on the Berkshire Dictionary of Chinese Biography. Educational, professional, and language-learning publications are also on the planning board. All these Berkshire China titles are being designed with a simple goal: to enable the leaders
of today and the citizens of tomorrow to work together to build a brighter future.

“China just won’t stop happening,” said my daughter Rachel when I complained about how hard it was to bring these five volumes to a conclusion. But when I considered speeding things by reducing the work to only four volumes, my son Tom reminded me—hissing the word sì, which means “four”—that sì sounds like the Chinese word for “death” and is considered bad luck. (It was Tom who realized we could use the colors that represent the five “elements” in Chinese traditional thought to differentiate the volumes of the Encyclopedia of China.) In truth, we have not brought the encyclopedia to conclusion, but we have managed to bring it to press. These five volumes—knowledge polished and pressed—set out much of what we know, and need to know, about China at the beginning of a new phase of human history.

How Berkshire Came to China

The Berkshire Encyclopedia of China evolved from our landmark six-volume Encyclopedia of Modern Asia, begun in 1998 and published to much acclaim in 2002 with Scribners. It was a project of exceptional complexity, inspired by my lifelong curiosity about Asia and much facilitated by my experience in working with international networks of scholars, beginning with the Encyclopedia of U.S. Foreign Relations, sponsored by the Council on Foreign Relations and published by Oxford in 1997. During the course of work on the Encyclopedia of Modern Asia I made my first trip to China, landing in Beijing in April 2001, the week China was holding the U.S. Navy surveillance plane, the EP-3, which had collided with a Chinese F-8 fighter jet and then crash-landed on Hainan Island. I was immediately engrossed by China. I could feel the energy and determination of the whole population. I relished the conviviality and humor of the people I met, and the sense of possibility I felt in the air along with an intense focus on what lay ahead—it was all irresistible. As an environmental author, two of whose books have been translated into Chinese, I was acutely aware of the influence, for good or ill, that China would have on my own and my children’s future.

But I knew nothing, really, about China. I decided that I needed to learn, and that I had to find ways to help other Westerners, young and old, learn about China. I hoped that with more knowledge, more ways to understand and connect, they too would feel this excitement—and a sense of shared possibility rather than fear. Having stayed in touch with many of our Encyclopedia of Modern Asia authors, it was fortuitous that the China editor for that project, Linsun Cheng of the University of Massachusetts, Dartmouth, agreed to join this new effort. He turned to a variety of Chinese reference sources in putting together the original article list, which ranged widely across all periods and knowledge domains, and included many interesting aspects of traditional Chinese culture, such as towpaths and ancient libraries. Although we had to drop some of those topics because of space constraints and lack of recent research, we expect to weave them into online and future print editions as our scholarly network in China continues to grow.

“A GREAT CLOUD OF WITNESSES”

This Encyclopedia of China is not solely the creation of those whose names you see on its pages. It has been inspired and spurred by many others: “a great cloud of witnesses.” Trying to explain how this publication fits into the history of Western study of China, that phrase popped into my Western-literature-trained mind. It comes from the New Testament of the Bible, Letter to the Hebrews (12:1), and is addressed as a rallying cry to a group of converts thought to be in danger of reverting to Judaism: “Therefore, since we are surrounded by such a great cloud of witnesses, let us throw off everything that hinders and... so easily entangles and let us run with perseverance the race marked out for us.” The author meant to reassure his readers that they were not alone; that even those who were not present with them constituted part of their community. The imagery, as translated from the Greek, suggests an athletic contest in a great amphitheater (“run with perseverance”). Many of those involved in the Encyclopedia of China are convinced that through scholarly cooperation—which, like running a race, can be as arduous as it is exhilarating—we can bridge differences, create new understanding, and build a better world and future for children in China, Western nations, and around the world.

My sense that there has been “a great cloud of witnesses” involved in this endeavor extends beyond that theme. There were scholars who did not say “yes” when invited to contribute to this encyclopedia, and some made
it plain that they did not believe that this work could be done. I am deeply grateful to those who joined our venture, but I am also grateful to those who said “no.” Their skepticism goaded me, and sometimes brought a laugh and renewed enthusiasm. One of my colleagues passed on the remark of a Chinese scholar who said that he hadn’t thought such a project was possible, “But somebody has the nerve to try. Best wishes to them.”

Encouragement came as word of the project spread (and as Berkshire began to publish other, smaller China-related books and a monthly newsletter, *Guanxi: The China Letter*). An e-mail from an eminent historian I kept before me during some of the most challenging months read, “Yours is a worthy cause. The world does need to know more about China. The Chinese are not all that good about telling foreigners about themselves, so an outside publisher is the best thing for them. All the best. Wang Gungwu.”

And a sense of cooperation was evident at the end, too, coming from some of China’s leading young social networking entrepreneurs. They worked with us to decide on the correct translation for the title and subtitle, *Berkshire Encyclopedia of China: Modern and Historic Views of the World’s Newest and Oldest Global Power* 宝库山中华全书: 跨越历史和现代, 审视最新和最古老的世界大国, and also helped to rename Berkshire itself (in Chinese) as 宝库山 (bāo kù shān), which means something like Treasure Mountain Reference Books. There were a dozen people, most of them in China, involved in this translation, including the volunteers at a company that translates English-language blogs into Chinese. In the course of the discussion, our friend Isaac Mao (who had recently visited us in Great Barrington, a small town nestled in the Berkshire Hills of western Massachusetts, and thus added the “mountain” to our company name) wrote that this was a great example of “crow wisdom.” He meant to type “crow,” but our American editor Mary Bagg thought at first that he was alluding to a Native American tradition—which wouldn’t have been surprising, given the rich diversity of our international exchanges.

**Special Challenges**

Publishing any multi-volume work poses a number of challenges, both logistical and theoretical/conceptual. For a “Western” publisher attempting a work on an “Eastern” subject, the difficulties take on a cross-cultural dimension, and require special attention at all levels of the process, from providing author guidelines that will be clear to scholars in many countries who work in diverse fields such as archeology, economics, politics, and zoology, to developing new editing manuals that included Chinese names, dates, and terms. Even something as straightforward and rule-bound as end-of-article citations proved complex, as we debated how to style Asian and Western names, dealt with transliterations and translations of article titles, and wrestled with differing ideas about what should be cited. Our aim has been to provide varied avenues for further reading, in English, Chinese, and a few other languages as well.

**Sensitivities**

Anyone who studies China knows that there are political and cultural sensitivities, and differences of viewpoint, to be taken into account. Our goal has been to present information about these viewpoints, and not to take sides, in the conviction that clear, accessible presentation will lead to greater understanding. Achieving clarity is not easy. Scholars can be influenced, sometimes unconsciously, by the prevailing philosophies within their disciplines—and all of us are culture bound. But a publisher can question assumptions and ask for clarification on points of fact or interpretation, an interaction that is necessary, intellectually fruitful, and often fascinating.

**Language Matters**

This is an English-language encyclopedia, but realizing that learning Chinese is part of learning about China, we’ve included many articles on language and linguistics, given every article an English and a Chinese title, and, whenever Chinese authors have provided it, included Chinese within the articles themselves. This is useful to Chinese readers and to students of Chinese, and will help the rest of us develop a greater comfort level with Chinese characters—the pictograms made by combining elements called “word radicals” (and a subject to which we devote an entire illustrated article)—and with transliteration, the presentation of the foreign word in a phonetic construction. (For our Chinese transliterations we
use pinyin, adopted after 1949, as opposed to the earlier Wade-Giles version.) This is a tricky thing, because transliterations are identical in all Western languages that use the Arabic alphabet. An Italian or Dane, for instance, has to interpret the sound of Beijing from the same string of letters as an English speaker.

But learning a language, of course, involves more than just recognizing and pronouncing words—and the way language is handled in a translated article shapes the content to some degree. Because many of our authors wrote originally in Chinese and, as is customary in Chinese universities, had their graduate students convert the articles into English, we have undoubtedly “lost in translation” certain nuances of meaning and expression. On the other hand, our American editors occasionally had to “translate” an English word in the submitted article—“cleavage,” for instance, when in context the author really intended “rift” or “split”—into an idiom more natural to the English-speaking ear. Knowing that even “literal” translation can be somewhat subjective, especially when writing about politically-charged topics, we also considered how Chinese readers might interpret our presentation of their native language. As Haiwang Yuan, one of our associate editors, put it: “As an encyclopedia, we are not to take a stand.” With that in mind he provided two translations for the article “Tibetan Uprising of 1959”: qıˇy ì $start_right_shift_1$ , meaning “uprising” from the exiled Tibetans’ point of view, and pànluàn 叛乱, or “insurgence,” as the Chinese would phrase it.

**DYNASTIES AND DATING DILEMMAS**

Readers often consider encyclopedias to be the ultimate authorities for defining dates throughout history—for everything from the three major eras of human development to China’s shortest dynasty. Exactitude is important, but it is often impossible. With ancient periods there are different calendars and ways of measuring time to consider, and the different experts encyclopedia editors themselves consult sometimes disagree. Sometimes events evolve rather than simply occur.

Nevertheless, to provide as much consistency as possible, we established an “Authority List” of dates. Many of our authors were agreeable to slight adjustments if their dates differed from ours. Others were helpful in revising their articles to make dating complexities, and inconsistencies that occur between Chinese and Western sources, clear to the lay reader. Charles C. Kolb provided the following explanation: “The highly complex period of the Southern and Northern dynasties has engendered lively scholarly debate about official and unofficial and regional/local dynasties whose names appear in the Chinese chronologies but are not always recognized as valid by Western scholars . . . [and even] China scholars acknowledge that there is disagreement on the year dates for this era. The dynastic subgroups referred to in this article may be best characterized as unofficial local dynastic units whose names appear in unofficial or altered official histories.”

Our custom of providing dates in parentheses in the text (for dynasties, political movements, and wars, for instance, as well as reign and life dates) puts events into historical context—as in “Cultural Revolution (1966–1976).” On occasion we needed to make decisions about dating that would allow us to be concise and appear consistent when events or governments overlapped. An example from the modern era involves dates for the Qing dynasty (1644–1912) and Republican China (1912–1949). Although this might seem straightforward to the general reader we have been diligent, when these periods get more than a referential mention, to explain that while the Republic of China was founded in the last days of 1911, the Qing emperor refused to abdicate until February 1912. In a similar circumstance, if an author made a reference to China’s “opening” in 1978, we suggested amending the date to 1978–1979 to reflect that opening was a process involving lots of political “phasing in and outs” rather than a dramatic about face.

Names of events can pose dilemmas as well. The War of Resistance against Japan (1937–1945), for example, is how the Chinese (and the Encyclopedia of China) refer to what the Western world calls the Second Sino-Japanese War. And although the Chinese were understandably focused first on Japan as their “personal” threat in those years, that war was eventually fought in the context of World War II in the Pacific. We’ve taken care to present these kinds of nuances so that our readers will have the benefit of several perspectives.

Another phenomenon that perplexed us was directional usage. Chinese people will often refer to a place,
such as Guizhou, as being in the southwest or to Shanghai as a southern city, where to a Westerner looking at China’s national borders it seems that Guizhou should be south-central China and Shanghai on the mid-east coast. The Chinese perspective, we learned, is not a geographical designation but one of population, thus Hebei and Hunan provinces, geographically mid-east, are considered central China. In our province and city articles, however, we have clung to the Western habit of orienting a place by its location on the map, and have provided a number of them throughout the encyclopedia as visual aids.

**Eight Encyclopedia of China Features**

1. Succinct, accessibly written (and many illustrated) articles, ranging from 500 to over 6,000 words, begin with a short summary or abstract and are arranged alphabetically in five volumes.

2. Articles fall into eight major categories (eight for good luck—it is no coincidence that the 2008 Olympics began on the eighth day of the eighth month, at 8:08 p.m.), with biographical entries a subcategory wherever relevant: Arts and Culture; Geography and Environment; Governance; Language and Learning; Organizations with a China Focus; Science, Technology, and Medicine; Society and Social Welfare; Values and Worldview.

3. Each article begins on its own page so it can be copied or printed for individual or classroom use. Page margins make it easy to copy articles on U.S. letter-size and international A4 paper. (Up to ten copies of three articles for use in a single course or classroom can be made at no charge—for further copies, please make payments via Copyright Clearance Center, www.copyright.com)

4. Article titles appear in English, Chinese characters, and a pinyin transliteration with tone marks, and Chinese characters and transliterations are used throughout articles.

5. Each article ends with a “Further Reading” section, provided by the author, which includes additional sources for research in (where appropriate) books; journals, newspapers, and magazines (in print or online versions); and websites.

6. Over 1,200 unique photographs, many with captions either adapted from the text or drawn from other sources to provide additional insight, enhance the visual appeal.

7. Maps, timelines, tables, and primary-source sidebars provide context (both historical and modern) and encourage more specific study; dozens of traditional proverbs reflect Chinese wisdom and (often) humor.

8. The index uses volume as well as page numbers for convenience, and includes pinyin (transliteration of Chinese characters) article titles and Chinese terms, too.

**Acknowledgements**

The idea of *guanxi*, loosely translated as “relationships” or “connections,” is one that intrigued me long before beginning work on the *Encyclopedia of China*, but its power and complexity became clear as time passed. We needed our editors’ and authors’ networks, and we found that our own networks expanded—and that people who had worked with us on other publications, on World History, Community, Leadership, and even Religion & Society, were able to help. There were serendipitous introductions to people that made certain aspects of this project possible, and even better than we’d dreamed. One was with Joan Lebold Cohen, whose photograph collection and passion for all aspects of Chinese life and society have transformed this work visually; we devote a page to her contributions separately.

Being introduced to Haiwang Yuan of Western Kentucky University was another event of great importance. Haiwang’s knowledge of China and his insight into the nuances of expressing Chinese concepts, as well as his cheerful willingness to answer questions at evenings and on weekends, right up until the final moment, have been invaluable. Another breakthrough came when Gregory Veeck, a geographer at the University of Western Michigan, suggested I call him if I needed some help finding authors. This proved a breakthrough with our geography and environment coverage, and Greg’s understanding of just how complicated the project was gave us a crucial psychological boost, too.

Many people gave us essential help at the last minute, and while I mention only two of them here as examples, there are others who also have our warm thanks. A long-
time Berkshire author, Winberg CHAI, stepped in to expand our coverage of Taiwan with several additional articles and the extensive updating needed after the 2008 presidential election, which has led to considerable reduction of tensions and increased economic cooperation. And Tony TAN provided an excellent article on “Adoption” that provides a comprehensive look at an important way in which people throughout the United States have direct personal connection with China.

As mentioned earlier, we are indebted to Isaac MAO, LEI Zhang (founder of Yeeyan.com), and Haiwang YUAN for renaming the encyclopedia. (The family names of all our contributors and biographical subjects are in capital letters to reflect that although in Chinese tradition the family name comes first, some Chinese have chosen to follow the Western treatment, family name last, whether or not they have Western given names.) An important change was the switch to 奄 from 幼稚, for the word China. Our advisers told us that this is acceptable by both Chinese on the mainland and Taiwan, as well as throughout the world, and that奄 better suggests the flavor of our coverage and the full span of the 5,000 or so years of Chinese history.

Some people who did not contribute articles gave important advice. Kenneth Lieberthal was particularly helpful on environmental topics, and we had a lengthy exchange with Harry Harding about how and whether to cover the concept of “Greater China.” Both provided ideas for the second edition. Our long-time friend Lester Brown, president of the Earth Policy Institute and author of Who Will Feed China?, helped us plan environmental coverage, as did Jennifer Turner and her colleagues from the China Environment Forum at the Wilson Center, who were particularly attuned to cutting-edge topics such as food safety. We are also delighted to publish the work of energy experts Mark Levine, Trevor Houser, and Christopher Webber.

Two experts on education in China whom we’ve worked with before, Ruth Hayhoe of the University of Toronto and Heidi Ross of Indiana University, came through in a big way, ensuring that our coverage of education of all types—from special education to university education—was extensive, something we considered of great importance because education is so highly valued in Chinese culture and has major implications for China’s future.

In addition, Judy Polumbaum of the University of Iowa and June Grasso of Boston University helped with final checks of our coverage. Judy helped with both modern media and historical figures, modern publications, and provided considerable encouragement during the process.

Human rights are probably the most problematic area for many people in understanding China. The subject got huge amounts of Western media attention during the period we were working on the Encyclopedia of China because of the riots in Tibet, the Olympic torch relay, and the Beijing Games in general. Western reactions led to a nationalistic backlash in Chinese and amongst overseas Chinese, and we expect to be doing more to help build awareness and understanding about this subject. Our coverage provides valuable historical perspective, and we have had the advice of a number of experts, including Stephen Angle, Minky Worden, and Sharon Hom.

An encyclopedia derives from human networks in existence but creates them as well, and these webs stretch round the world. When I wrote to Chatham House about a China program taking place during the days when I would be in London, a welcome came back from the program director with word that his articles for the Encyclopedia of China were nearly finished. This fortuitous meeting with Kerry Brown has already led to the launch of another reference project, the Berkshire Dictionary of Chinese Biography (2010).

One of the best established networks in the field is that of the National Committee for United States–China Relations, and we have benefited from the guidance of its current leadership, Stephen Orlins and Jan Berris, and are grateful for permission to include many photographs from its extensive collection. Other organizations took the trouble to dig into old files for historical photographs, too, and many authors helped us locate the fascinating visual material seen here.

Before mentioning Berkshire’s small in-house staff, I must acknowledge our reliance on several professionals—Peggy Hollway, Martin Lubin, Steve Tiano, and Brad Walrod—who have been with us since our first independent imprint began, just over four years ago, and have become adept in handling Chinese characters, transliterations, and tone marks, and who take care not only with the design and layout but who sometimes send e-mails in the middle of the night to point out editing errors. (We like to think they just cannot resist reading the articles.)
Our copyeditors deserve recognition for their adaptability to and enthusiastic engagement in the plethora of new rules and standards involved in publishing a huge work about China, and for research contributions, too, as they worked to ensure that coverage would be accurate, up-to-date, and easy to understand.

Editor Mary Bagg stepped into a new role when I asked her if she could “pre-proof” the entire encyclopedia before composition. This is an extraordinary thing to take on. In general, large works are divided up between a group of editors and proofreaders. See, for instance, the entry “Yongle Dadian (Great Compendium of the Yongle Reign).” This 11,095-volume work, with 22,877 chapters and a sixty-chapter-long table of contents, was put together by a staff of compilers, editors, and scribes during a five-year period and completed in 1408. In an e-mail sent to project coordinator Bill Siever during the final push before publication, Mary wrote: “Check this out. The numbers have put our task into perspective.” The consistency between articles and graceful phrasing of even articles on technical, data-heavy topics are the result of her devoting several months to meticulous review, and review, of every article.

There have been quite a number of Berkshire staffers involved in the Encyclopedia of China during its three years’ development, and all contributed in different ways. Those who have been with the project during its final stressful months, none by education or background China specialists, deserve special mention here. Bill Siever landed in the Berkshires and at Berkshire Publishing in the summer of 2008 and was immediately plunged into China—an immersion that proved his mettle in a multitude of ways. It was Bill who would arrive at the office at 4 or 5 a.m. on snowy winter mornings, and who not only had to learn about style sheets and authority lists but pinyin and Wade-Giles. He handled considerable pressure from all directions with an aplomb that I could only marvel at, and be grateful for.

Tom Cotton Christensen has been fully immersed in the encyclopedia since graduating from Grinnell College in December 2007, but in a sense he and his sister Rachel grew up with this project, having first visited China in 2001 on a trip our family took during work on the Encyclopedia of Modern Asia. He then learned Chinese and has had several long stays in Shanghai and Beijing, as well as a couple of shorter jaunts. While he sometimes thinks that his mother set him on this China path, I often wonder if his interest in China and adeptness at speaking Chinese ignited my interest in making the Encyclopedia of China a primary publishing focus for Berkshire.

Anna Myers came to us as a graphic design intern after earning an MFA. Her sensitivity to Chinese motifs—she is half Chinese-American—and her ability to transform a variety of photos, illustrations, and design elements into cohesive themes, made her the perfect person to help shape the visual content of these volumes. Anna is the daughter of one of our contributors on Chinese music, John Myers, who teaches at the nearby Bard College at Simon’s Rock, where Anna and Tom were classmates. Ashley Winseck, another of Tom’s schoolmates (this time from Undermountain Elementary in Sheffield) proved an able editorial assistant, dealing earlier on with authors’ responses to queries and later gathering extracts (and inspiring ideas) for the sidebars to our articles.

Synchronicity, as I mentioned at the beginning, has characterized this project. Bill, Tom, and Ashley were all born in a year of the Ox, the Encyclopedia of China is being first published in 2009, another year of the Ox, and the People’s Republic of China, founded in 1949, also had its beginning in a year of the Ox. This year has already been an important one in global history, with unprecedented economic challenges and evolving new relationships amongst the world’s great nations. The PRC’s sixtieth anniversary in October 2009 will be yet another chance to take stock of China’s growing importance on the world stage.

Finally, my thanks to all those who have made this publication possible need to include the caveat that errors remaining are my responsibility—and now the responsibility of our readers, too, as we trust that everyone who uses this work will see that a project of this scale and importance needs their perceptions and knowledge. We welcome information—research results, reports, book recommendations, and of course offers to contribute further articles on the many topics we have not had space to include in this first edition of the Berkshire Encyclopedia of China.

Karen CHRISTENSEN 沈凯伦
Great Barrington, Massachusetts
Meeting Joan Lebold Cohen, an art historian who specializes in Chinese art and film, was a stroke of good fortune that has, as readers will see, immeasurably enriched the Berkshire Encyclopedia of China. Many of the photographs on these pages were taken by Joan beginning in 1972, soon after the momentous visit by Richard Nixon to China, when she and her husband Jerome Alan Cohen, an eminent expert on Chinese law, began extensive travels throughout the country. From those first days Joan recorded all she could with her camera—while exploring the landscape, touring factories or agricultural communes, wandering through markets, or attending official meetings. Joan documented the China she saw—which was already beginning a period of rapid change—from sophisticated Shanghai to the vast but sparsely populated terrain of Xinjiang.

As a student of China history and art—and later as a lecturer and teacher—Joan developed an astute sense of how the real and often rugged world she was experiencing connected to China’s past. She shot scenes of the mountains, from which mist rose when the early morning rain stopped, that evoke the work of Chinese master-painters through the ages. She could transform a mundane image into a work of exquisite beauty: In Rice Seedlings, a close-up of a water-logged paddy, she took advantage of shimmering, reflected light to conjure a painterly tradition akin to Monet and his water lilies. But Joan was just as likely to be captivated by the people she observed, met, and befriended in China. A photo of weary tourists huddling on a bench near the Forbidden City, for instance, serves as both a haunting group portrait and a study of individual isolation. Myriad candid photographs—of children and adults alike—show Joan’s ability to engage shy but impish smiles.

Joan and Jerome began to collect the work of Chinese artists in the early 1970s; they witnessed both the excessive restrictions of the late-Mao period and the gradually increasing freedom artists achieved during the post–Cultural Revolution years from 1979 to 1981. The Cohens recently gave their collection to the art museum at Smith College, Joan’s alma mater. Post-Mao Dreaming: Chinese Contemporary Art, the exhibit that celebrates the Cohen collection and other recent additions to the museum, provides a window into the era when Chinese artists, emerging from the constraints of thirty years of Maoist Communism (1949–1979), began to reclaim their individuality.

Over the years Joan has written and provided the photographs for an impressive list of books. The New Chinese Painting, 1949–1986 introduced recent generations
of Chinese artists to the West; other titles include Yunnan School: A Renaissance in Chinese Painting; Angkor, Monuments of the God-Kings; and Buddha. She is co-author with her husband of China Today and Her Ancient Treasures (3rd edition, 1986). Joan served as curator for four exhibitions of contemporary Chinese art, as well as for the photographic exhibition New York: The City and Its People, which was shown in Beijing. Her photographs have been widely exhibited and published and are represented in public and private collections in the United States and Asia. She lectured at Tufts University/School of the Museum of Fine Arts in Boston for twenty-two years and is currently a research fellow at Harvard University’s Fairbank Center for East Asian Studies, an associate of the Columbia University Modern China Seminar, and a frequent contributor to ArtZineChina.com.

We at Berkshire are especially grateful to feature Joan Lebold Cohen’s work as an integral part of ours, especially because we believe, as did the sixteenth-century author Gaspar da Cruz, of the Portuguese Dominican Mission in Asia, that, “China is much more than it sounds, and the sight must be seen and not heard, because hearing it is nothing in comparison with seeing it.” (The quotation comes from the first Western book published about China, Tractado em que so cõtam muito por esteso as cousas da China [Treatise in which is told many things about China], published in 1569.)

More information (and a virtual gallery of Joan’s photographs) is available at www.joanleboldcohen.com
Abacus

Suàn pán 算盘

Considered to be the first computer, the abacus has been used since ancient times by a number of civilizations for basic arithmetical calculations. It is still used as a reliable reckoner (and one that does not require electricity or batteries) by merchants and businesspeople in parts of Asia and Africa.

The abacus, or counting plate (suan pan), is a manual computing device used since ancient times in China as well as in a number of ancient civilizations. The Latin word *abacus* has its roots in the Greek word *abax*, meaning slab, which itself might have originated in the Semitic term for sand. In its early Greek and Latin forms the abacus was said to be a flat surface covered with sand in which marks were made with a stylus and pebbles.

The Chinese abacus as we know it today evolved to become a frame holding thirteen vertical wires with seven beads on each wire. A horizontal divider separates the top two beads from the bottom five, sometimes referred to as the heaven and the earth beads. The beads served as markers representing quantity, and the beads’ position on the vertical wires represented value.

A skilled abacus user performs addition, subtraction, multiplication, and division quickly and easily, without having to depend on electricity to produce a readout; the “readout” itself cannot be lost or erased except manually.

Because of the traditional Chinese use of 16 as an important standard of measure, the Chinese abacus is particularly useful for calculations using a base number system of 2 and 16.

Chinese sources document wide use of abaci by 190 ce, with popularization during the Song dynasty (960–1279) and printed instructions for their use appearing in the 1300s during the Yuan dynasty (1279–1368). By the Ming dynasty (1368–1644), the Chinese abacus had taken on its modern form and had become an integral part of business and financial accounting. This basic counting machine spread by the 1600s to Japan and then to eastern Russia, with small modifications in the number of beads above and below the divider.

Among storekeepers and small businesses in China, the abacus remained a standard piece of office equipment.

The heaven and earth design of the abacus has remained unchanged for centuries.
An abacus sits on the countertop in a neighborhood grocery store. Small shops in China, like this one in the basement of an apartment block in the Eastern District of Beijing, still use the abacus to add sums. PHOTO BY JOAN LEBOLD COHEN.

until the 1980s. A good-quality abacus is generally about 2 feet wide by 1 foot tall and made of sturdy brass with hardwood beads.

Academia Sinica is the leading academic institution of Taiwan and plays a major role in the field of Chinese studies. Its graduate program recruits students for its eleven PhD programs.

Academia Sinica, founded in Nanjing in 1928, is the most prominent academic institution in Taiwan (Republic of China). Although it is affiliated directly with the Presidential Office, Academia Sinica, located in the capital city, Taipei, enjoys independence in formulating its own research agenda. Its major tasks are to conduct academic research in sciences, humanities, and social sciences, as well as to provide guidance, coordination, and incentives to raise academic standards in Taiwan. In 2004 Academia Sinica established the Taiwan International Graduate Program to train scholars; it recruits five to ten graduate students every year for each of its eleven PhD programs.

Academia Sinica has made great progress in recent years. An increasing number of research papers written by its faculty members, which numbered 1,150 in 2001, are appearing in international journals. Some journals, published by Academia Sinica itself, such as Zoological Studies and Statistical Sinica, have received international recognition. Academia Sinica plays a major role in the field of Chinese studies. For example, the archaeological findings by researchers at the Institute of History and Philology have, in combination with written documents, led to a virtual rewriting of ancient Chinese history, pushing back the span of Chinese history by many centuries.

The president of Academia Sinica is Dr. Yuan-tseh Lee, a 1986 Nobel laureate in chemistry. The convocation (a ceremonial assembly of members of a college) consists of 199 members (academicians), including five ethnic Chinese Nobel laureates.

Acrobatics

Chinese acrobatics, called “variety art” (zaji) in Chinese, is one of the most widely viewed types of Chinese cultural performance. The acrobatic acts seen today are packaged for global consumption and are similar to the Western circus, but many of the acts have traditional roots and a long history unique to China.

The precise origin of acrobatics (zaji) in China is unknown, but historical records and ancient relics, such as relief carvings, show that acrobatics achieved imperial recognition no later than the Warring States period (475–221 BCE). In that era of constant warfare acrobatics that emphasized strength and agility developed in conjunction with the ruler’s encouragement of developing exceptional battle skills. Other acrobatic acts, such as walking on stilts and juggling, functioned as entertainment at village harvest celebrations. Other possible origins of acrobatics include shamanistic ritual, martial arts, and theater.

During the Qin dynasty (221–206 BCE) acrobatics that combined theatrical roles and athletic feats, often involving wrestling between men or with animals, was performed for the imperial court. During the Han dynasty (206 BCE–220 CE) acrobatics was an integral part of the “Hundred Entertainments,” a type of variety show that also included music, dance, martial arts, and magic.

Early Acts

The scholar and scientist Zhang Heng (78–139 CE) described in his “Ode to the Western Capital” an acrobatic theme show that was performed in the royal palace.
acts included balancing on a pole, walking on a rope, jumping through hoops, performing handstands, and performing the conjuring act “turning a fish into a dragon.” These acts are still performed today, although they have been modified for modern audiences.

Stone engravings that date back to the Han dynasty illustrate numerous types of acrobatic acts that showcased strength and agility, including juggling, handstands, and rope walking, and feats that involved poles, balls, barrels, carriages, and galloping horses. One relief shows an acrobat balancing on seven discs as three acrobats hang upside-down from a cross that is balanced on his head.

Due to the patronage of Han emperors, acrobatics was integrated into large-scale and extravagant performances, a tradition that lasted for years. The Silk Roads promoted cultural exchange with Persia (Iran) and the Roman Empire. Acrobatic shows were shown to foreign dignitaries and guests visiting China, and also performed for the Han court. In 108 BCE Emperor Wu Di hosted a royal show for visiting dignitaries, and a performer sent by the king of Parthia also performed for the emperor.

Acrobatic shows continued to be performed for the imperial court during the Tang dynasty (618–907 CE). Certain acts flourished, including acrobatic acts on horses, animal training, and pole climbing, in which an acrobat balances a pole on which many more acrobats are balanced. A poem written by Bai Juyi (772–846 CE) and a mural in the Dunhuang grottoes illustrate these performances.

During the Song dynasty (960–1279) acrobatic shows left the palace and entered the markets. Acrobatics was performed in town markets along with other types of performances, such as singing, storytelling, and drama. Juggling, in particular, flourished. Itinerant performers and professional acrobatics troupes and training schools also developed during this time.

The status of acrobatics decreased drastically during the Ming and Qing dynasties (1368–1912). Acrobatics became a performance art that was learned almost entirely through apprenticeship or that was passed down as a family business through the generations. Family troupes performed at markets or made their living by touring fairs and performing at public theaters. Despite the dedication needed to succeed as an acrobat, people

Juggling a fiery baton is one of the Kaifeng Acrobatic Troupe’s most spectacular acts. Photo by Joan Lebold Cohen.
who became acrobats, along with prostitutes and thieves, were classified as belonging to one of the nine unsavory professions.

In the late nineteenth century and early twentieth century Chinese acrobatics began gaining greater admiration from the West. After the founding of the People’s Republic of China (PRC) in 1949 the Chinese government paid more attention to acrobatics as a performance art and founded the China national Acrobatic Troupe in 1957.

Especially since the 1980s acrobatics have come to be viewed as representative of Chinese culture for people all over the world to admire. In October 1981 the China Acrobatic Arts Association was established. Formal training at academies has developed, and students begin their training at an early age. In an annual competition for the academies, acrobats representing troupes from all over China compete for medals. China now has over 120 acrobatic troupes and an estimated twelve thousand acrobats.

Road Show

Acrobatics has played an important role in cultural exchanges between China and other nations. In the past thirty-five years Chinese acrobatic troupes have toured more than one hundred countries throughout the world. Since the 1990s acrobatics has become packaged as a complete theme show, with greater attention to choreography, music, costumes, lighting, and special effects. The troupe Beijing Acrobats debuted overseas in 1986, and the Chinese State Circus began touring Europe in 1992. In addition to acrobatics, the shows often include performances of kung fu, Beijing opera, and variations on the traditional dragon dance and lion dance. Chinese acrobatics is now featured in Las Vegas shows and Hollywood films.

In its emphasis on strength, balance, and agility, Chinese acrobatics is similar to its Western counterpart. In general, focus is placed on the head, waist, and legs. However, the conceptual basis, training techniques, and acrobatic practice are also influenced by China’s tradition of martial arts. Acrobats strive to appear calm and steady on the tightrope and to maintain balance between the light and heavy in feet-balancing acts. Another unique characteristic is the use of farming tools or household items as props, seen in the commonly performed acts of balancing vats on the head, twirling cups or saucers, and diving through hoops, as derived from the grain sieves used by farmers. Balancing acts with tables, chairs, and cycles are relatively new. Many acts are also tied to Chinese folk practices, such as the performance of the Chinese yo-yo, or diabolo. Contortion, in which the human body is dramatically flexed, is not unique to China but is a featured act in most Chinese acrobatic shows.

Acupuncture ▶
Acupuncture

Acupuncture is an ancient Chinese medical treatment that involves inserting needles at specific points in the body to release blocked qi (life energy), which results in healing. The practice is used today in China (as well as in the West) to treat diseases in nearly every branch of medicine, often in conjunction with the burning of medicinal substances and herbs.

The ancient medical treatment called acupuncture, which uses very fine needles inserted at specific points along the body to heal ailments and provide relief from pain, is still a viable part of traditional Chinese medicine and has gained popularity in Western medicine as well. The *Huángdì Neǐjīng* (Canon of Medicine), compiled between 475 BCE and 23 CE, is the oldest extant medical book that mentions acupuncture. One of its components, the *Líng Shū* (Canon of Acupuncture), describes nine instruments, some of which are still used. Techniques for making bamboo needles and for casting bronze needles for use in acupuncture developed during the Shang dynasty (1766–1045 BCE). Acupuncture developed widely in China during the Song dynasty (960–1279), the Jurchen Jin dynasty (1125–1234), and the Yuan dynasty (1279–1368). However, the treatment was banned for general use by decree during the Qing dynasty (1644–1912) because it was perceived as being suitable for application only to the emperor.

A medical worker at a neighborhood clinic, located in the basement of an apartment block in the Eastern District of Beijing. Behind him are the charts that guide his application of acupuncture for the treatment of various ailments. PHOTO AND CAPTION BY JOAN LEBOLD COHEN.

Despite its being banned, acupuncture continued to flourish in general use. In the United States, although it...
had been popular in the Chinese-American community for more than one hundred years, non-Chinese Americans became more aware of acupuncture after President Richard Nixon's 1972 visit to China.

An understanding of acupuncture requires an some knowledge of the concepts of channels and collaterals. In Chinese medicine channels are the main trunks that run lengthwise through the body, and collaterals are their connecting branches. Together they connect the superficial, interior, upper, and lower parts of the body. Qi (life energy) courses through the channels. The twelve regular channels include the three yin channels of each foot and hand and the three yang channels of each foot and hand. Yin and yang are the basic, complementary principles of which all phenomena partake. For example, introversion, wetness, and cold are yin characteristics. Extroversion, dryness, and heat are yang characteristics. The eight extra channels are du, ren, chong, dai, yinwei, yangwei, yinqiao, and yangqiao.

Acupuncture points (or acupoints) are distributed along the channels and collaterals; 361 channel points and 231 common points are named in Chinese and also are named using the Roman alphabetical and Western numerical systems. For example, the often-used acupoint zusanli, which is located along the channel connecting the stomach to the foot, is internationally named “S-36.” When a practitioner inserts acupuncture needles at the points, their stimulation releases blocked qi, which in turn results in healing.

Acupuncture is used to treat diseases in nearly every branch of medicine in China, whether it is cardiology or obstetrics, dentistry, or infectious diseases. Acupuncture techniques also have embraced such new technologies as laser and electrical stimulation. In Chinese hospitals
where acupuncture is performed, the acupuncture section is called the “department of acupuncture and moxibustion” (moxibustion is the burning of medicinal substances, usually herbs, on the acupoints for therapeutic effect). Although the primary treatment in the department is acupuncture, moxibustion also plays an important role.

Even as Western medicine becomes more common in China in the twenty-first century, the practice of acupuncture continues, especially in hospitals that rely on traditional medicine and those that combine traditional and Western techniques.

Adoption
Shōuyǎng 收养

Most abandoned or orphaned children in China are adopted by relatives, but an increasing number of orphaned children are being adopted by families in foreign countries, including the United States. The China Center for Adoption Affairs applies strict guidelines in approving adoptive families; the results are well-qualified adoptive parents and successful social and academic adjustment of the children.

Since the normalization of relations with the People's Republic of China in 1979, exchange programs have brought together Chinese scholars, students, teachers, policy makers, and business people. These personal contacts have been an important part of developing better relations and new partnerships with other countries. But another type of exchange is having an impact, as a wide range of American couples, affluent and sometimes influential, have adopted Chinese children, most of them daughters. Since 1995, China has been the largest source of foreign-born children adopted in the United States. By the end of 2008, over 70,000 Chinese children had been adopted into American families.

Abandoned Children and Their Care

In 1979 China enacted what is commonly known as the one-child policy to limit most married couples to only one child (exceptions are made for ethnic minority groups). While the intention of the policy was to reduce population growth, one unexpected consequence of this policy was a drastic increase in the abandonment of female infants. Birth parents of these abandoned babies are mostly married peasants in rural China who have already had two or three daughters. Because child abandonment is against the law, parents usually leave their children with little identifying information, in public places at night or early in the morning to avoid legal trouble. Abandoned children whose parents cannot be located by police are considered legally orphaned.

The motive for abandoning a female infant is usually the parents’ inability to pay the fines for violating the one-child policy, often because they have already paid heavy fines for violating the policy once or twice before.

While there are no official statistics, it is estimated that at the end of 2002 there were about 300,000 to 400,000 orphans in rural China who were probably cared for by relatives (Shang Xiaoyuan et al. 2005). About 50,000 children (95 percent of whom were children abandoned by their parents) were cared for in state-run children’s welfare institutes or in collectively owned rural welfare institutions. Orphanage children range in age from newborn to late teens; they also range in physical condition from very healthy—the abandoned children’s prenatal experience in China has been considered better than that of many abandoned children in Russia and Eastern Europe because drinking, smoking, and teenage pregnancy among rural Chinese women are very rare—to severely disabled with conditions such as cerebral palsy, for example. Most abandoned boys have physical disabilities, some as minor
as a cleft palate, or mental disabilities. Most girls do not have a physical handicap, but have been abandoned as a result of the one-child policy and Chinese society’s preference for boys.

Orphanages (called Child Welfare Institutes or Social Welfare Institutes), usually located in or near a city, are typically gated and off-limits to locals and visitors. They often have a small clinic on site. The size of the orphanage can range from small (less than fifty children) to quite large (several hundred children). Operating budgets usually come from provincial and central government as part of the civil affairs budget. Most orphanages are inadequately equipped to care for and educate children.

In the orphanages, children are usually divided into different age groups. Older children are required, if capable, to help care for the younger ones. The children’s daily routines include scheduled feedings and/or meals, organized group learning, and other activities. Caregivers are usually women from local communities. The caregivers provide the best care they can, but due to a large caregiver to child ratio, one-on-one care is rare if not impossible. Orphanages have recently started utilizing local families to provide part-time or full-time foster care for some orphans.

As noted, most orphaned and abandoned children do not go to orphanages; some are brought up by relatives, but many may simply be unaccounted for. These children, especially those in rural areas, often live in poverty without access to social services. Government-funded subsistence allowances are available to orphaned/abandoned urban children and vary from region to region, but even the largest stipends are less than ordinary children’s living costs. Funds to provide the “five guarantees” (i.e., food, clothing, housing, medical care, and burial expenses) to orphaned and/or abandoned children in the countryside come from villages and towns. But the amounts of these funds are decreasing with agricultural taxation, putting more children at risk for inadequate care.

**Domestic and International Adoption**

Under the leadership of China’s Ministry of Civil Affairs, the China Center for Adoption Affairs (CCAA) in Beijing is the headquarters for domestic and international adoption: it governs policy and regulations. For international adoptions, the CCAA sets the quota, handles the paperwork, and matches children with potential foreign adoptive parents. By law, only an orphan under the age of fourteen is eligible for adoption. The orphanage must publish local newspaper ads regarding a child under its care and allow six months for birth parents to claim the child. The child is legally declared an orphan after that period and is thus allowed to be adopted. Open adoption
from the orphanage is almost never a possibility as the orphanage has no knowledge of the identity of the child’s birth parents.

Chinese citizens can adopt either from the orphanages or from other channels (e.g., private adoption, kinship adoption). There are no statistics regarding kinship and private adoption within China. For Chinese citizens to adopt a child from the orphanage, they must first register with the county-level civil affairs office where the child’s orphanage is located. In order to qualify for an adoption certificate, the applicants must be at least thirty years of age, infertile (with medical evidence), and medically and physically capable of caring for children. They also need to show proof of residence and marital status. A single male adopting a female child is additionally required to be at least forty years older than the child. Upon receiving the adoption certificate, the applicants are allowed to pick one child from three to four eligible children. Little is known about the development of domestically adopted Chinese children.

China first allowed a small number of children to be adopted by foreign families in 1985, when twenty children were adopted into the United States. (From 1985 to 1989, seventy children were adopted by American families.) In 1991, to relieve the heavy demands of a drastically increased number of abandoned children in the state-run child welfare institutes, China enacted adoption laws to permit a larger number of children to be adopted internationally. The United States adopts the most children. Since 1995 China has been of the largest source of transracial adoption in the United States, accounting for over 35 percent of the children involved in U.S. international adoptions. By the end of 2008, 71,753 Chinese children were adopted into American families (Families with Children from China, 2008). Chinese children have also been adopted into families in Australia, Belgium, Canada, Denmark, Finland, France, Iceland, Ireland, Italy, the Netherlands, New Zealand, Norway, Singapore, Spain, Sweden, and the United Kingdom. There are no statistics as to the number of children adopted into many of these countries.

The Good Earth

Pearl S. Buck, an eminent twentieth-century novelist who won both the Pulitzer and Nobel prizes, was an adoptive mother and early proponent of interracial and international adoption. Buck was born in China to missionary parents and spent the first half of her life there. Her best-known book, The Good Earth, contains much about the plight of Chinese girl children and the suffering of parents who sometimes sold them into slavery to avoid starvation.

O-lan had been rinsing the rice bowls with a little water and now she piled them in a corner of the hut and looked up at him from the spot where she squatted.

“There is nothing to sell except the girl,” she answered slowly.

Wang Lung’s breath caught.

“Now, I would not sell a child,” he said loudly.

“I was sold,” she answered very slowly. “I was sold to a great house so that my parents could return to their home.”

“And would you sell the child, therefore?”

“If it were only I, she would be killed before she was sold . . . the salve of slaves was I! But a dead girl brings nothing. I would sell this girl for you—to take you back to the land.”

“Never would I,” said Wang Lung stoutly, “not though I spent my life in this wilderness.”

But when he had gone out again the thought, which never alone would have come to him, tempted him against his will. He looked at the small girl, staggering persistently at the end of the loop her grandfather held. She had grown greatly on the food given her each day, and although she had as yet said no word at all, still she was plump as a child will be on slight care enough. Her lips that had been like an old woman’s were smiling and red, and as of old she grew merry when he looked at her and she smiled.

“I might have done it,” he mused, “if she had not lain in my bosom and smiled like that.”

Research shows that families in these countries have adopted children from over 530 Chinese orphanages in all twenty-three Chinese provinces (China considers Taiwan the twenty-third province), four of the five autonomous regions (no children have been adopted internationally from Tibet), and four municipalities (Beijing, Chongqing, Shanghai, and Tianjin), while the leading sending provinces are Guangdong, Hunan and Guangxi (Tan 2006).

QUALIFICATION AND COST OF INTERNATIONAL ADOPTION FROM CHINA

Since it first permitted international adoption, the CCAA has modified its regulations several times. In December 2002, the agency reduced the quota of single parent adoption from 33 percent to no more than 5 percent. In May 2007, in response to a decrease in the number of children available for international adoption, the CCAA drastically changed its policy, allowing only married heterosexual couples aged between thirty and fifty-five to adopt from China. The couple must have been married for a minimum of two years if it is the first marriage, five years if it is a second or third marriage, and no more than two previous marriages are allowed for either spouse. There must be no more than four children living in the home. Additionally, in section III of the new CCAA regulations, couples may not adopt if they have one or more of the following conditions:

1. AIDS
2. Mental handicap
3. Infectious disease within infective stage
4. Binocular blindness, binocular parallax (problems with depth perception), or monocular blindness; no ocular prosthesis
5. Binaural hearing loss or language-function loss (adoption of special needs children who have identical conditions will be exempt from this limitation)
6. A function or dysfunction of limbs or trunk caused by impairment, incompleteness, numbness, or deformation; severe facial deformation
7. Severe disease that requires long-term treatment and affects life expectancy, such as malignant tumor, lupus erythematosus, nephrosis (kidney disease), epilepsy, etc.
8. Major organ transplant within the previous ten years
9. Schizophrenia
10. Medication for severe mental disorders, such as depression, mania, or anxiety neurosis, within the previous two years
11. Body mass index over forty (BMI = weight in kilograms/height in meters²)

Further CCAA regulations make the following stipulations:

IV. Either the husband or wife must hold a stable occupation. The family annual income reaches $10,000 for each family member, including the prospective adoptee; family net assets should equal $80,000. Family annual income does not include welfare income, such as relief fund, pension, unemployment insurance, or government subsidy.

V. Both the husband and wife have an education at or above the level of senior high school, or vocational skills training at the same level.

VI. There must be fewer than five children in the family under the age of eighteen years, and the youngest one should have reached the age of one year. Adoption of special needs children will be exempt from the restriction as to number of children under the age of eighteen.

VII. Neither the husband nor the wife can have a criminal conviction. Both behave honorably, have good moral character, and are law-abiding. Neither the husband nor wife the has any of the following:

VII a. A history of domestic violence, sexual abuse, abandonment or abuse of children (even if not arrested or convicted).

VII b. A history of taking narcotics like opium, morphine, marijuana, cocaine, heroin, methamphetamine, or medication for mental diseases that may cause addiction among human beings.

VII c. A history of alcohol abuse or alcohol over-consumption within the previous ten years.

Adoption applications are given consideration on a case-by-case basis when either the husband...
or the wife has less than three criminal records of slight severity with no severe outcomes, the time from correction of the wrong has reached ten years, or has less than five records of traffic law violation with no severe outcomes.

VIII. The adoptive parents are able to understand adoption and expect to provide a warm family for the orphaned children (or children with handicap and disability) via adoption and to meet the needs of the children adopted and ensure their good development. They have a correct understanding of intercountry adoption as well, and are fully mentally prepared for the potential risks within intercountry adoption and for the situations of children adopted, such as potential diseases, developmental delay, post-placement maladjustment, etc.

IX. The adopters, in the adoption application letter, make clear promises of being able to accept post-placement follow-ups and offer post-placement reports as required.

The cost of adopting a Chinese child from an orphanage can range from US$20,000 to US$25,000. At the time of receiving the child, the adoptive parents are required to make a cash donation of US$5,000 to the child’s orphanage to help improve the living conditions of the children who remain in the orphanage.

PROCEDURE FOR INTERNATIONAL ADOPTION FROM CHINA

According to Families with Children from China (FCC), adopting a child from China includes three phases: assembling application paperwork, waiting, and the trip to China to adopt the child. The application paperwork, generally known as the dossier, consists of ten or so documents that actually go to China and other documents required by local state, county, and adoption agency rules. After all of the documents are collected and authenticated, the entire package is sent by the adoption agency to the China Center of Adoption Affairs (CCAA) in Beijing. One of the major documents in the application is called a home study. This document, prepared by a licensed social worker employed by an agency with an approved China adoption program, describes the prospective family. A typical home study will involve three visits with the social worker, one at home and two at the social worker’s office. The family must have recommendation letters sent directly to the social worker. The final document, which usually runs to six pages or so, can be thought of as a short biography of the parents and an evaluation of whether they will be acceptable parents. It takes approximately thirty to thirty-six months from receipt of the completed dossier to referral of a child for adoption. Travel to China to pick up the child is normally scheduled three months after referral. Some of the major adoption agencies in the United States include Chinese Children’s Adoption International (CCAI), China Adoption With Love, Inc. (CAWL), and Alliance for Children.

The actual adoption usually occurs at a hotel near the orphanage. The adoptive parents first meet with the officials from the civil affairs offices and orphanage directors to complete the paperwork and make the cash donation. Following that, the child is handed to the parents. The transition time is usually brief. Parents are usually not permitted to visit the child’s orphanage.

Characteristics of Chinese Children at Adoption

The average age of a child at the time of adoption is about thirteen months. Most of the children have been reared in an orphanage since early infancy. Some have received foster care. Most children are girls, and about half of the children show some degree of developmental delay. While fetal alcohol syndrome, HIV, and prenatal drug exposure have not been reported, lead poisoning is common.

Children who were adopted through the special-needs program (called the Waiting Child Program) are usually older and/or have special needs due to physical conditions that can range from very minor (e.g., birthmarks, missing one finger), to moderately severe (e.g., cleft palate), to severe (e.g., cerebral palsy).

Post-Adoption Development

While initially, it is not uncommon for some Chinese children to show worrisome behavior such as sleep disturbances, eating problems, or attachment issues, research conducted in Canada, Ireland, the Netherlands, Norway,
and the United States has provided compelling evidence that Chinese children adjust remarkably well in the adoptive home. Their language acquisition, social and emotional adjustment, and later academic performance have all been reported as either similar to or more favorable than their non-adopted peers. Such a favorable adoption outcome has not been reported among children adopted from Eastern Europe or Latin America. Many researchers

Historical illustration of “A Baby Tower” from the 1885 book *Child Life in China*, written by Mrs. Bryson, a missionary from the London Mission in Wuchang. The author describes baby towers, infamously reputed to have been a means for disposing unwanted children, most often female, at the time of their birth. Although missionary reports of such methods of infanticide appeared in Western media, especially after the founding of the Republic of China in 1911, the author reviewing Mrs. Bryson’s book in *The China Review*, shortly after the book’s publication, comments on never having seen one during extensive travels in the southern part of the country. Bryson’s account resonates today when considering China’s one-child policy—of which an unexpected outcome was the dramatic increase in the number of abandoned baby girls.
speculate that the Chinese children’s favorable adjustment results from a combination of the birth mother’s reasonably good prenatal care, a fairly decent orphanage experience, and positive adoptive family environment (e.g., highly educated, high-income-earning parents). Chinese children adopted by single parents show similar adjustment to Chinese children adopted by married couples. Long-term outcomes (e.g., adjustment in later adulthood) are unknown. One aspect of concern in these children’s future development lies in their possible desire to search for birth parents. It is unlikely that most children will be able to locate their birth parents due to the complex circumstances surrounding child abandonment in China. So far, there is only one child who was adopted by a Dutch couple who successfully located the birth parents.

Probably due to their favorable adjustment, about 75 percent of the families that have adopted from China adopt additional children from China. Recently some post-adoption disruptions have been reported. This mainly occurs to children who were adopted at an older age. As most of the adopted Chinese children are girls, many scholars and policy makers are becoming increasingly concerned about the gender imbalance in China. In some provinces the ratio is now 114 males for every 100 females for children under the age of four.

To help foster a sense of pride about the adopted children’s cultural heritage, many adoptive parents actively involve their children in various Chinese cultural activities: language class, kung fu class, celebrating Chinese festivities. As the children get older, many parents go with their children to China to visit their orphanages and to learn about China. Major travel agencies have also been established to cater to heritage trips; one example is Lotus Travel, Inc.

Other online communities are also very active. Some of the organizations, such as Raising China Children, focus on Chinese adoptions in general. Other groups have a more specific focus, including groups for families of children adopted from certain regions of China and groups organized around specific developmental issues and topics, such as attachment, special needs, identity, and general post-adoption adjustment.

Adoptive families have also established charitable organizations to help improve the lives of children in the orphanages. One of the largest organizations is Half the Sky Foundation. Other foundations such as Our Chinese Daughters Foundation and China Care also play very active roles in improving children’s lives.

Chinese trade, investment, and aid contribute to growth in Africa, but China’s growing presence on the continent has caused rising international concern as observers debate China’s strategic motivations.

China’s presence in Africa is expanding, increasingly complex, and the object of growing controversy both among African nations and countries around the world. Chinese accounts of contemporary China-Africa relations often begin with stories of Tang dynasty (618–907 CE) explorer Du Huan, said to have visited Egypt, Sudan, and other areas of Africa, or the multiple voyages to eastern Africa by Ming dynasty (1368–1644) Admiral Zheng He, and end with the observation that China’s contacts with Africa from the earliest times have been friendly, mutually beneficial exchanges.

Although Chinese isolationism during the late Ming dynasty and Qing dynasty (1644–1912) brought an end to officially sponsored trade missions by China’s imperial government, beginning in the 1950s the People’s Republic of China pursued relations with the newly independent countries on the continent, frequently making commitments of foreign aid, such as financing for the massive Tanzania–Zambia railway project. Beijing’s African diplomacy had many aims at the time, including asserting solidarity with the Third World as its relationship with Moscow deteriorated and limiting the number of countries granting diplomatic recognition to the Nationalist (Kuomintang) government in Taipei, Taiwan. In addition, prior to the 1990s China provided material and organizational support, including arms and training programs, to revolutionary movements in Africa. As China’s liberalizing economic reforms took hold in the 1980s, the impetus and nature of Chinese ties with Africa began to change, and relations with the continent came to be seen by China in the context of safeguarding its economic security and related strategic goals of enhancing global influence and international prestige.

Expanding Chinese Presence

Today China is Africa’s second-most important trading partner after the United States, having recently surpassed France, and is poised to become its most important as early as 2010. Since the mid-1990s China’s trade with countries on the continent has expanded rapidly along with its rising demand for raw materials and imported oil, supported by the country’s official “go out” (zou chuqu) policy, which encourages Chinese firms to invest abroad and includes a commitment by China’s top leadership to use state resources to ensure the country’s energy security. In 2000 two-way trade between China and Africa stood at less than $1 billion a year; it had reached $73 billion by 2007, and China’s Customs Administration predicted that trade will have exceeded $100 billion by the end of 2008. African countries are importing increasing quantities of China-produced apparel and machinery, and imports from Africa have become increasingly important to China. For example, Angola became China’s greatest single source of foreign oil in 2006; Burkina-Faso...
and Mali now supply 20 percent of China’s cotton imports; and mineral-producing countries like the Democratic Republic of the Congo, Zambia, and South Africa are meeting a growing share of Chinese demand. Africa now accounts for around 30 percent of China’s oil imports, 80 percent of its cobalt imports, and 40 percent of its manganese imports. China’s most important trading partners on the continent are Angola (19 percent), South Africa (19 percent), Sudan (8 percent), Egypt (6 percent), and Nigeria (6 percent). In 2007, looked at in aggregate, African countries ran a small ($1.1 billion) trade surplus with China.

Along with trade, countries on the continent are seeing an unprecedented flow of Chinese investment dollars into their economies. In the early 1990s Chinese foreign direct investment in Africa was less than $10 million; estimates suggest it may have reached $6 billion by 2006. Chinese firms have seized opportunities where those of other countries have been deterred by perceptions of risk. For example, in the 1990s, when civil war held back other investors, China National Petroleum Corporation (CNPC) developed oil fields in Sudan; after conflict broke out in Ivory Coast in 2002, and its traditional economic partners, such as France, distanced themselves, China increased its investment in its cocoa sector. Although Chinese foreign direct investment in Africa stands at only about 3 percent of total Chinese overseas investment, its share is expected to rise as it diversifies. In 2007 China’s Industrial & Commercial Bank took a 20 percent stake in South Africa’s Standard Bank, and China’s textile manufacturers, seeking both to lower costs and to find a way around U.S. and European quotas, are building factories in Africa.

Today Chinese businesses can be found in forty-nine African countries, with approximately eight hundred Chinese state companies operating on the continent. Increasing numbers of individual Chinese are also pursuing economic opportunities in Africa, with the overwhelming majority in South Africa, followed by Zambia, where one of three planned Chinese-developed special economic zones will be located. According to some estimates, Chinese nationals in Africa now total about 550,000—more than the number of U.S. (70,000) or French citizens (100,000). Chinese tourists to Africa have also been
growing by double digits in recent years. Increasing numbers of Africans also live in China as people from the forty-eight countries in Africa with which China has diplomatic relations, seeing opportunity in China’s growing exports to their countries, move to China. A reported ten thousand people from the continent now live in Guangzhou (Canton) alone, many engaged in buying low-end textiles and other finished goods for resale in Africa. Most African businesspeople come to China on short-term visas but find ways to extend their stays, with the result that cities like Guangzhou are developing African neighborhoods where representatives from the continent’s myriad cultures interact with the Chinese way of life. African merchants, mostly from Nigeria, Mali, and Ghana, have been arriving in such large numbers to do business in Guangzhou’s clothing and textile trade centers that in November 2008 Kenya Airways instituted mainland China’s first nonstop route from Africa, between Nairobi and Guangzhou. Some reports suggest that Chinese authorities have sought to limit migration from African nations to China by tightening already-restrictive visa requirements in early 2008, although others indicate that this development can be attributed to general changes in Chinese immigration requirements in preparation for the 2008 Olympics.

Alongside the expansion of Chinese commercial interests in Africa, many African nations have been the beneficiaries of Chinese foreign aid, both from the Chinese Export-Import Bank and from humanitarian projects. According to official Chinese figures, China had given $5.74 billion in aid to Africa by 2006, contributing to eight hundred projects, with many more in the pipeline. This aid figure does not include debt relief, which added up to nearly $1.4 billion to thirty-one heavily indebted and least-developed African countries. By official count, China had provided more than eighteen thousand scholarships to Africans and had sent more than fifteen thousand medical personnel to countries on the continent. China’s Export-Import Bank plans to spend $20 billion in Africa in the next three years—about the same expenditure planned by the World Bank during that period. A World Bank study estimated that through mid-2006, Export-Import Bank loans to Africa totaled over $12.5 billion in infrastructural development alone, directed at projects concentrated in Angola, Mozambique, Nigeria, Sudan, and Zimbabwe.

Complex Relationship

China’s relationship with Africa is becoming increasingly complex. Along with development assistance and growing commercial linkages to the continent, China has cultivated deeper political, military, and cultural relationships with African nations, aimed to support its economic interests but also aimed toward other international objectives. Having abandoned policies of the era of Chinese Communist Party leader Mao Zedong that championed revolutionary and national liberation movements in Africa, Beijing’s political relationships with African countries are conducted government to government. China’s adamant defense of the inviolability of the sovereignty of African states, going back to principles asserted at the 1955 Bandung conference of developing nations, has been rewarded by backing from African countries in international forums where China has been the object of Western-led international criticism. This support and the tendency by African states toward bloc voting in multilateral organizations have proved highly beneficial to China, resulting in the repeated defeat of human rights proposals directed against China at the United Nations and contributing critically to the International Olympic Committee’s decision to award the 2008 Olympics to Beijing, for example. China also expects to draw on support from countries on the continent for its positions on multilateral trade issues and revisions to international economic rules. In addition, expanding relationships with African countries have benefited China in its ongoing efforts to reduce Taiwan’s international space, not only by weakening the appeal of Taiwan’s attempts to court African states for diplomatic recognition but also by drawing on African support to keep Taiwan out of international organizations.

China has also made military cooperation and arms sales an important facet of its relationship with African countries. China has military-to-military contacts with more than forty countries on the continent. Fourteen of China’s military attaché offices are in African countries; and seven African countries (Algeria, Egypt, Namibia, Nigeria, Sudan, Zambia, and Zimbabwe) have reciprocal offices in Beijing, with another twelve African countries maintaining resident military offices in their embassies to China. Although only 6 to 7 percent of all arms supplied to Africa currently come from China, Chinese weapons
have found eager buyers in Sudan and Zimbabwe—both countries under a Western arms embargo. Ethiopia is another leading destination for Chinese arms. Nigeria has also become one of China’s best African customers; after efforts by the U.S. Congress to block or delay patrol boats for use in Nigeria’s troubled delta region, Nigeria has chosen to procure Chinese military supplies, including missiles and fighter jets. China has also agreed to train Nigerian specialists in satellite operations.

Africa has been an important focus of China’s growing participation in international peacekeeping operations, with the majority of its peacekeeping troops engaged in operations on the continent. It has participated in peacekeeping operations in Liberia and has contributed troops to U.N. missions in Sudan, the Democratic Republic of the Congo, Ethiopia and Eritrea, the Ivory Coast, and the U.N. Mission for the Referendum in Western Sahara. In addition, China committed three hundred engineers and several million dollars in support of U.N.–African Union peacekeeping operations in Sudan.

Along with political and military relations, Beijing has significantly expanded cultural and educational exchanges with Africa in the last few years, and in the framework established at the November 2006 Beijing Summit of the Forum on China-Africa Cooperation (FOCAC) is committed to doing even more. The Chinese government is establishing Confucius Institutes offering Chinese language training at universities in several countries, with three already under way in Kenya, Rwanda, and South Africa and five more in the planning stages. In addition, at the FOCAC China agreed to send Chinese agricultural experts to Africa and to establish demonstration sites, committed to train fifteen thousand African professionals in three years beginning in 2007—double the number of scholarships for African students—and to send several hundred Chinese young people to Africa by 2010, through the program Chinese Young Volunteers Serving Africa, to volunteer in fields from education to sports to health and agriculture.

**China’s African Presence and International Concerns**

China’s growing presence in Africa has met with rising international controversy as international observers, including human rights groups, other countries with interests in Africa, and Africans themselves debate China’s strategic motivations and conduct on the continent. China’s development aid and economic engagement are associated with unprecedented economic growth in Africa—5.8 percent in 2007. Chinese-financed transportation and communications infrastructure projects have helped some countries overcome seemingly intractable bottlenecks and leapfrog technologically in some sectors. Chinese money linked to commercial deals has helped finance new public buildings from presidential palaces to sports stadiums. Further, as part of its stated “win-win” Africa policy, China has promised duty-free treatment for African goods to help diversify Africa’s export market. To date, China’s trade with Africa has followed patterns established by its other main trading partners.

Others see China’s deepening role in Africa in a different light. Generally, African governments and elites have welcomed the largesse and debt relief from the world’s biggest developing country as an alternative to Western aid and see Chinese trade and investment as a much-needed source of growth. But China’s expanding economic presence is also generating new concerns and tensions. Some people opposed to China’s growing footprint in Africa argue that China is just the latest power to exploit African resources, and they complain about many Chinese corporate practices. Others contend that Chinese infrastructure agreements underbid local firms and include stipulations requiring the use of Chinese labor and therefore contribute inadequately to skills and technology transfer and to generating potential local employment. In Mauritius complaints have centered on the employment of Chinese rather than local workers in Chinese-constructed factories. Elsewhere local workers in Chinese-owned mines and factories report harsh and unsafe working conditions. The flood of cheap Chinese-made goods into local markets is another area of concern. Some calculations attribute the loss of 250,000 textile-related jobs in Nigeria to Chinese imports. The impact of Chinese-led development on the environment is another source of concern amid evidence of Chinese companies violating local environmental and conservation regulations, including reports that a major Chinese oil company prospected for oil in a nature reserve in Gabon, and that Chinese companies have been engaged in illegal logging in several African countries.
Because many of the Chinese businesses operating in Africa are state owned, the behavior of Chinese firms is generally ascribed to Chinese government policies. But anti-Chinese sentiment has also taken the form of deliberate attacks on Chinese nationals, including kidnappings and arson directed at Chinese-owned businesses. What China’s presence means for the continent is beginning to influence national political debate as well. In Zambia’s 2006 elections opposition leader Michael Sata ran for president on an anti-Chinese platform, nearly unseating the incumbent.

Chinese lending practices have also raised concerns on the part of traditional donors who have decried the opacity of some of China’s loan agreements and the extension of new loans by China to countries pursuing debt forgiveness under the Highly Indebted Poor Countries (HIPC) initiative. Some, such as Transparency International, worry that the absence of conditions tied to Chinese aid also undermines international efforts to encourage improved political and economic governance. Some observers also are concerned that the politically illiberal Chinese development model is thwarting international hopes for more open and democratic governance in African countries. Beijing’s willingness to do business with regimes with a record of human rights violations, such as Khartoum and Harare, has been criticized as helping to shield those regimes from critical international censure and worsening threats to human security. Also criticized has been the willingness of Chinese to pay bribes overseas to facilitate commercial agreements, a practice that reinforces the corrupt and opaque practices linked to political instability across the continent.

Currently, however, China-African relations appear to be entering a new phase. On the one hand, as African countries recognize they can play one resource-hungry buyer off against the other, they appear increasingly

willing to risk losing deals with China for better terms and conditions. For example, pressure from South African trade unions resulted in quotas on Chinese textiles to that country beginning in early 2007; Ghana’s government has sought to create conditions for its private sector to take the lead in building economic relationships with Chinese partners in recent years; and in May 2008 Nigeria’s government rejected Chinese offers of a nonconcessionary loan for a high-speed rail project that it wishes to develop under private-sector management. On the other hand, not all African countries have the capacities of South Africa, Ghana, or Nigeria, and some African leaders have begun to push for collaboration across the continent to develop an Africa-wide strategy for relations with China.

At the same time China has appeared increasingly concerned about the impact of its role in Africa on its international image and prestige. Chinese leaders have left meetings with Zimbabwe’s dictatorial president Robert Mugabe off their itineraries during recent visits to the continent, for example. In addition, after years of international pressure to leverage its economic ties with Sudan to bring an end to the atrocities in the Darfur region, China has moved away from its strict policy of “non-interference” toward more public efforts to persuade Khartoum to agree to international cooperation in crafting a peace settlement. In 2007 Beijing appointed a special envoy on Darfur, and Chinese president Hu Jintao began to speak publicly about the need for the Sudanese government to do more to end the crisis. In the months ahead of the Beijing Olympics, China went on the diplomatic offensive, explaining its opposition to sanctions and highlighting its pivotal role in Khartoum’s agreement to allow U.N. and African Union peacekeepers into the country, as well as its contribution of several hundred Chinese engineers to this deployment. China’s galloping economic growth and surging demand for energy and raw materials assure its continued interest in deepening its role in Africa in the coming years. With the emergence of alternatives to both Western and Chinese investment, including India and oil-rich states from the Middle East to Russia, African countries will have the opportunity to manage their relations with their Chinese counterparts increasingly strategically. China’s role in Africa should therefore be seen as an evolving one, shaped not only by Chinese economic and security objectives but also by international competition and the capacity of African countries to assert their own interests.

Agricultural Cooperatives Movement

The agricultural cooperatives movement, which sought to move rural China beyond small family farming, was a significant step in the socialist transformation of the Chinese countryside. It was achieved without much turmoil despite the excesses associated with various stages of the process. Once collectivization was completed, though, some of the excesses laid the seeds for the radical policies of the Great Leap Forward.

The agricultural cooperative movement was a major campaign by the Chinese government to transform rural China in the 1950s. After land reform China’s agricultural economy operated on the basis of small family farming. However, the small size of family farms and the use of simple tools not only left many peasant households vulnerable to natural disasters but also limited the scale of production. The latter made it difficult for the state to mobilize resources to supply sufficient agricultural commodities needed for industrialization. More importantly, family farming based on private ownership of land created conditions for the emergence of new class polarization in the countryside, a phenomenon that could have posed political problems for the Chinese Communist Party (CCP), whose victory in the civil war was based largely on the support of poor peasants. Hence, the party leadership decided almost immediately after the completion of land reform to organize peasants into mutual aid teams and cooperatives in preparation for the transition to socialism.

Despite differences over the pace of collectivization, a consensus existed within the CCP leadership on the socialist transition in the countryside. As stipulated in the party’s first decision on such an issue on 15 December 1951 (published in February 1953), the party’s basic policy was that such a transition would evolve through three stages. The first stage was to organize peasants into mutual aid teams. This stage was to be followed by the establishment of elementary cooperatives. The final stage was to be the completion of the socialist transformation of agriculture with the formation of advanced cooperatives or collective farms.

Mutual Aid Teams

Experiments with mutual aid teams and cooperatives began soon after the completion of land reform in some liberated areas even before the founding of the People’s Republic of China in 1949. But major momentum developed when the CCP Central Committee issued its first decision on mutual aid and cooperation at the end of 1951.

The formation of mutual aid teams was based largely on traditional forms of mutual aid in rural areas. Mutual aid teams usually consisted of several peasant households working together in the spirit of voluntary participation and reciprocity. Members of mutual aid teams retained their private ownership of land, means of production, and outputs. Mutual aid teams were formed primarily to...
exchange labor, draft animals, and implements. Compensation was based on mutually agreeable terms.

Two types of mutual aid teams existed. One was the smaller elementary type with three to five households. It operated on a seasonal or temporary basis and was limited to certain kinds of important farm work such as planting and harvesting. After the work was done the team would disband. The other type was more advanced. It was larger, consisting of six to ten or more households. Operating on a year-around basis, its members over time might well accumulate a small amount of common property, such as farm tools and draft animals.

In both types of mutual aid teams, land, farm tools, and draft animals were still privately owned, and each peasant household continued its own production. The formation of mutual aid teams, however, made it possible for members to exchange labor and other means of production, an especially important factor for the poor, who often needed to exchange their labor for the use of the tools and draft animals of the middle peasants. Politically, the alliance forged in this process could also serve to isolate the rich peasants.

After publication of the policy guidelines regarding the socialist transition in the countryside in February 1953, mutual aid teams developed rapidly. Their number grew from 4.68 million in 1951 to 9.93 million in 1954, with the participation of more than 58.4 percent or more than 68.5 million of all rural households.

Elementary Cooperatives

Experiments with elementary agricultural cooperatives began at about the same time as the initial formation of mutual aid teams in various parts of the countryside. Given the failure of mutual aid teams to prevent the emergence of a new group of rich peasants, and the increasing polarization along class lines in the countryside, the government decided to shift the focus of rural work from mutual aid teams to elementary agricultural cooperatives.

The cooperatives were several times larger than mutual aid teams and usually consisted of thirty to forty households. Initially peasants were organized into elementary cooperatives based on the same principle of voluntary participation and mutual benefits. Elementary cooperatives were regarded as semisocialist organizations because members would retain ownership of the land and other means of production but would pool these resources as shares under a unified management. Under the new system members were paid according to the work done as well as with dividends drawn from each member’s contribution of land and other capital assets such as farm implements, farm transport, and draft animals.

Elementary cooperatives organized peasants more efficiently than did mutual aid teams. The pooling of land under a unified management would eliminate a major structural weakness of Chinese agriculture: small, dispersed, and uneconomic landholdings. The consolidation of fragmentary pieces of land under unified management would also expand the size of fields and the scale of production.

agricultural activity by eliminating boundary lines between individual plots.

Elementary cooperatives were popular with the rural population not only because members were allowed to retain their ownership of land and other assets but also because participation was based on the principle of voluntarism and reciprocity. In addition, members were allowed to keep a certain amount of land as “private plots” (zi liu di), which usually did not exceed 5 percent of the size of individual landholdings. Given their popularity, the number of elementary agricultural cooperatives grew rapidly from around 300 at the end of 1951 to 497,000 at the end of 1954. By June 1955 the number of elementary cooperatives was around 650,000, with the participation of about 17 million rural households.

But the rapid growth of elementary cooperatives also created difficulties and confusion in management. First, how to accurately evaluate work and pay turned out to be a challenge. Disputes over dividends paid for land contributions also drove a wedge between the middle and poor peasants. All these problems were caused by the complexity involved in organizing large groups into collective action but also by the lack of well-trained personnel in the countryside to fill leadership positions. Because of this lack of appropriate leadership skills and proper incentive structure, most of the elementary cooperatives formed during this period were not efficient. Many had trouble with even simple tasks such as bookkeeping.

The worst problem, though, was not management and organization but rather the weakening state capacity to extract resources from rural areas. Largely because of the slaughtering of livestock and lack of accumulated fertilizer to improve the land, China suffered two grain crises from the spring of 1953 to the summer of 1955. Lower-than-expected grain production in 1953 and 1954, and increased consumption by the rural population, created uncertainty over continued delivery of sufficient grain to the state. The government responded to the situation by establishing a unified method for the purchase of grain. For the government the issue is not only output but also the insufficient amount of grain and cotton allotted for industrialization and urban consumption. In fact, part of the reason for accelerating development of the cooperatives movement was to reduce the number of producing units and to improve planning so the government could have better control over the sales of agricultural commodities and consumption.

But subsequent food shortages in some areas, which resulted from excessive grain purchases at a time of slow growth in production, caused widespread anger and resistance in the countryside. In response, the government implemented a system of assessing peasants’ grain obligations that was known as the “three fix” (fixed quotas for production, consumption, and procurement). This system was designed to ease peasants’ anxieties over their tax burdens.

The agricultural cooperatives movement went through cycles of expansion and contraction. For example, it accelerated in the winter of 1952 but slowed in the spring of 1953. It expanded again in the winter of 1954 only to contract in the spring of 1955. This pattern was clearly linked to the ongoing debate within the CCP leadership, but it also reflected the problems of disorganization and over-ambitious planning, excessive methods by local cadres,

In this wood-block-print-style propaganda poster, peasant youth criticize their former landlord, celebrate the arrival of Communism, and dance with soldiers from the People’s Liberation Army. PHOTO BY JOAN LEBOLD COHEN.
and the alienation of more productive peasants—all factors that were related to the rapid expansion of the cooperatives. When China experienced a grain crisis in the countryside in the spring of 1955 that led many peasants to suffer from severe food shortages, Deng Zihui, central government leader in charge of agriculture, advocated a cautious approach to the pace of collectivization. This approach was initially endorsed by Liu Shaoqi who was in charge of the day-to-day operation of the party at the time, and it was agreed to by CCP leader Mao Zedong himself.

But in the spring of 1955, and again on July 31 of the same year, Mao changed his position drastically with a famous speech, “On the Cooperative Transformation of Agriculture.” In this speech he made a strong case for accelerating the pace of the agricultural cooperatives movement to prevent the emergence of a new class of rich peasants and a dangerous new class polarization in the countryside. At the same time he launched a campaign against what he perceived “rightist deviations.” He accused Deng Zihui and those within the CCP leadership who advocated gradualism of underestimating the immense enthusiasm for socialism among the poor and lower middle peasants, denouncing them as “tottering along like women with bound feet” instead of leading the movement in the front.

Mao’s harsh criticism of right-wing conservatism silenced different voices. Under such circumstances few officials had the courage to argue for a gradual approach again. Subsequently Mao’s view was adopted as a resolution at the Sixth Plenum of the Seventh Central Committee of the CCP in October of 1955. The resolution accelerated the formation of agricultural collectives and provided impetus for a new campaign to change the Chinese countryside. Thus the high tide of socialist transformation predicted by Mao at the end of 1955 quickly became a self-fulfilling prophecy. The agricultural cooperatives movement quickly picked up steam as zealous local cadres exerted all their efforts to outdo each other in the implementation of the new party policy. Under pressure to show results and eager to avoid being accused of “rightist conservatism,” local and regional authorities tended to carry out the new policy with far more speed than the party resolution originally envisaged. Thus, in the months after the plenum various provincial party committees revised their plans and competed with each other for early completion of collectivization.

The race to set up cooperatives soon swept aside any remnants of the previous cautious approach based on gradualism and experimentation. Looking for quick results, local cadres frequently ignored earlier principles of voluntary participation and mutual benefits. Many peasants were pressured to join the cooperatives against their will when local cadres exerted political and economic coercion. For example, cadres frequently withheld credit from private farmers who were unwilling to join.

The race to set up cooperatives soon swept aside any remnants of the previous cautious approach based on gradualism and experimentation. Looking for quick results, local cadres frequently ignored earlier principles of voluntary participation and mutual benefits. Many peasants were pressured to join the cooperatives against their will when local cadres exerted political and economic coercion. For example, cadres frequently withheld credit from private farmers who were unwilling to join.
Many were forced to organize into large-scale collectives directly from individual farming or small-scale mutual aid teams. Many of the proven methods of gradualism through trial and error were cast aside under mounting pressures for speedy transformation to socialism. By the beginning of 1957, the main task of the socialist transformation of agriculture had been fulfilled with virtually the entire countryside being reorganized in advanced cooperatives.

Advanced Cooperatives

Advanced cooperatives usually consisted of two hundred to three hundred peasant families. Under the new system, when a peasant became a member his land and other principal means of production were transferred from private to collective ownership. Rents for land shares and other capital assets were abolished. Payment for members of advanced cooperatives was based solely on work points earned according to types of work performed. However, peasant households continued to receive small plots of land for private use.

Mao’s about-face decision to accelerate the transition to full collectivization in the summer of 1955 arose out of contradictory goals: he wanted China to achieve rapid industrialization and yet to continue small-scale farming. Given the rising demand of grain for the development of industry and urban consumption and the slower-than-expected rate of grain production, rapid transition to collective agriculture thus became imperative. As a result, the principle of voluntary participation and gradualism gave way to the new political priority of speedy socialist transformation through collectivization.

Many local officials were worried that their political loyalty would be questioned if they remained behind other regions in the race to set up cooperatives. Therefore they competed, trying to outdo each other in this new campaign. Subsequently, the cooperatives movement went through cycles as Mao and the central party leaders set goals, the provinces outstripped those goals, the central party then revised its targets upward, and the provinces again overfulfilled them. Even at the end of 1955 Mao estimated that another three to four years would be needed to complete the establishment of the advanced cooperatives at the most basic level. But zealous local and provincial leaders again overshot this target; in the rush to collectivize, the earlier cautious policy of advancement by stages was abandoned. While Mao continued to warn against leftist excesses in the autumn and winter of 1955–1956, he was impressed by the enthusiasm and speed of collectivization.

Mao and his allies interpreted this race to collectivize as a sign to further accelerate the socialist transformation
of the countryside. In December 1955 Mao personally edited and prefaced a book, *The Socialist High Tide in China’s Countryside*. He estimated that the formation of elementary cooperatives could be basically accomplished in a single year—1956—instead of the previously estimated three or four years with total completion in 1960. On 25 January 1956, Mao called a meeting of the Supreme State Council at which he demanded the adoption of the National Program for Agricultural Development 1956–1957, which stipulated that in some areas where conditions were favorable, all peasants should be brought into the advanced type of cooperative by 1957. Accordingly, the program envisioned that the conversion of the whole countryside into advanced cooperatives should be accomplished by 1958.

The new agenda abandoned the earlier gradual approach based on voluntary participation and mutual benefits. After Mao’s call to speed up the pace of the socialist transformation, the collectivization movement reached a fever pitch. In June 1955 only 529 advanced agricultural cooperatives existed, with the participation of forty thousand peasant households. By the end of 1956 the number of advanced cooperatives reached 544,000 million, with the participation of more than 107.4 million, or 88 percent of all peasant households. By the end of 1957 the socialist transformation of agriculture was accomplished, and the number of peasant households organized into advanced cooperatives reached 96 percent.

One reason for the cooperatives movement’s rapid acceleration was shrewd strategy. The government not only provided incentives for a majority of the peasants to join the cooperatives but also left them with little choice but to cooperate. Credit cooperatives, supply and marketing cooperatives, and unified purchase of grain and other key commodities increasingly restricted the space of private economic activities for rich peasants. With economic resources gradually channeled to the cooperative sector, the incentive structure was altered to encourage peasants to join the cooperatives. During the “high tide” the cancellation of land dividends in the advanced cooperatives amounted to a direct transfer of economic resources from the rich peasants to the poor. The latter had the numerical dominance from which the party could draw support to push those who were still hesitant to join the collectives.

This rush to establish cooperatives created numerous problems. Many policies that accompanied the rush, such as direct planning over the size of sowing areas, output, and the closing of most of the rural markets, caused a major disruption in agricultural production. As a result, many officials in the central government realized the seriousness of the problems and the dissatisfaction of the peasants over the rush to collectivization. Subsequently, when the rigidity of the newly formed advanced cooperatives became increasingly obvious, a period of adjustment followed in 1956–1957.
Starting in April 1956 and continuing into the summer of 1957, some of the excessive policies associated with the high tide of collectivization were reversed. Steps to deal with problems were taken under a program that became known as “opposing rash advance.” These steps included placing new emphasis on setting realistic targets, coordinating planning and quality in output, increasing the scope of peasants’ private production, reopening some limited rural markets, and reducing the size of the cooperatives. The adjustments continued until they were swept away during the Great Leap Forward by a new wave of agrarian radicalism to organize peasants into much larger communes.

The agricultural cooperatives movement marked an important step in the socialist transformation of the Chinese countryside. It was a significant development beyond land reform to move rural China toward a more equal distribution. Overall, despite the excesses associated with various stages of the process, this was accomplished without much turmoil. First, the rents and dividends paid for the use of land and other assets were capped below compensation paid for labor. Then these rents and dividends were eliminated altogether, and pay was based solely on the type of work performed. By pooling together resources through the establishment of cooperatives, the scale factor contributed to the increase of grain production. However, once collectivization was achieved, the leadership embarked on more ambitious programs that led to the disastrous Great Leap Forward of 1958-1961.

Agriculture has been crucial to the growth and development of Chinese civilization since ancient times. Over the past century many significant changes in agriculture have reflected large-scale political upheaval in China. Today Chinese agriculture thrives through the development of technology, but it continues to face challenges related to food security in a changing environment.

Agriculture has played an integral role in the development of civilization, society, and the rise of the modern state. Throughout China’s long history the importance of providing the nation’s people with food has been linked with the political stability of the state. Emperors and dynasties have gained and lost their political power based on their ability to ensure that the food supply is sufficient to feed the people. An understanding of agriculture’s development in China over centuries offers a unique perspective into the growth and expansion of a large and thriving civilization, not just a view of the ruling elite’s ability to maintain power. During the past fifty years agricultural production in China’s rural countryside has undergone significant transformations. From land reform and collectivization to the household responsibility system, Chinese agriculture has indeed been affected by larger political structures.

Throughout premodern China agricultural production relied on simple tools and organic methods of production. In his early study on Asian agriculture in *Farmers of Forty Centuries*, the historian F. H. King asserts that the United States and other Western countries have much to learn from Asian agriculture. His book portrays the ability of Asian civilizations to develop agricultural technologies that have produced food in a sustainable way to feed their people over centuries. He draws on experiences along the east coast of China, from Hong Kong and Guangzhou (Canton) to Manchuria, to show how...
the Chinese have developed agricultural techniques that have allowed the land to produce large amounts of food continuously. The recent introduction of mechanization (although still rather limited because of the abundance of human labor) and chemicals has placed new challenges on Chinese farmers and the environment.

The agricultural challenges that China faces are certainly intensified by the combination of its being the world’s most populous nation and having limited agricultural land. China is home to about 21 percent of the world’s population but only occupies about 6.5 percent of the world’s land area. Further complicating this disproportionate ratio is that much of China’s land is unsuitable for crop cultivation. Ninety-four percent of China’s
population lives in the eastern and southeastern regions of China, whereas the northwest and west are mountainous, dry, and difficult to navigate. Moreover, industrial and urban development in the east and southeast is beginning to threaten the ideal growing conditions found in these temperate and subtropical regions.

Major crops in China include grain (rice, wheat, corn), meats (all major types), cotton, soybeans, rapeseed (and other oils), tobacco, sugar-yielding crops (sugarcane and beets), peanuts, and tea. Apples and other commodity fruits and vegetables have also become major export crops in recent years.

Traditional Agriculture

Agricultural production began in China in the loess lands (unstratified loamy deposits found in North America, Europe, and Asia) of the Wei and Huang (Yellow) River valleys around 6500 BCE. By 4000 BCE large farming villages had spread throughout China. Millet was the main grain domesticated at this time. Animals were a part of these villages and, along with wild plants gathered, supplemented the millet diet. Both short- and long-grain varieties of rice appeared before 5000 BCE but did not gain popularity until techniques were developed later to assist with irrigation and improve yields. During the Shang civilization (1766–1045 BCE), food preparation and consumption were considered to have become ritualized and complex. In ancient China the development of food and agriculture was part and parcel of the development of Chinese civilization; cities were expanding, art was flourishing, villages were establishing rituals surrounding the consumption of the food they produced.

Chinese agriculture took shape during the Qin (221–206 BCE) and Han (206 BCE–220 CE) dynasties. The imperial government established a comprehensive agricultural plan to substantially increase yields and technology during this time. These developments, including land terracing and water irrigation, led to the definitive shaping of the food system during the Song dynasty (960–1279), when food production became rational and scientific. Agricultural techniques developed during the Song dynasty, including the organic preparation of soil, maintenance of high-yielding seeds, complex irrigation systems, and the commerce of crops, remained relatively unchanged until the mid-twentieth century. Regional, elaborate banquet cuisine developed at this time, and foreign trade opened China’s economy to foreign influences. New crops that foreigners introduced were adopted and thrived.

With the development of rational agricultural techniques, the Chinese were forced to face the issue of population growth. After the Song dynasty the growth of population dramatically increased through the twentieth century. Throughout the Ming (1368–1644) and Qing (1644–1912) dynasties, as well as Republican China (1912–1949) and the early years of the People’s Republic (1949–), China’s farm economy responded to the demands of a rising population. During this period China’s population expanded by eight to ten times the level it had been in 1368, the beginning of the Ming dynasty. As the population grew, agricultural production expanded to meet the needs of the people with no dramatic changes in farming techniques or rural institutions. The expansion of agricultural production at this time is attributed to the abilities of the population to adapt to changing conditions.

In the 1930s John Lossing Buck, a professor of agricultural economics at Nanjing University, conducted a survey of Chinese agricultural management from 1921 to 1925. This survey covered 2,866 farming households during the republican period. Results were published in 1937 as Land Utilization in China and have proven useful in modern times in understanding the transition of agriculture at the turn of the twentieth century and before the Communist revolution.

Agriculture in the Maoist Period

On 1 October 1949—after the War of Resistance against Japan (1937–1945, also known as the Second Sino-Japanese war), World War II in Asia, and China’s civil war—the Chinese Communist Party (CCP) founded the People’s Republic of China. With a base of support from the peasants in the countryside, the Communist leadership decided that land reform would be one of its first priorities. Throughout the countryside of the new Communist China, land was taken from landlords and distributed evenly among peasant households. The Communists’ first Five-Year Plan (1952–1957) called for a socialist transformation of agriculture. Mutual aid teams and primary
and advanced producers’ cooperatives were established to achieve this socialist ideal. Collectivization efforts proved successful; by 1957, 93.3 percent of the peasant households were in advanced producers’ cooperatives and 3.7 percent in lower-level (primary) producers’ cooperatives.

The ideal of self-sufficiency drove the collectivization of agriculture. Along with the political and economic changes accompanying the communes, agricultural output quotas were established, primarily to promote self-sufficiency in grain production. Regardless of its geographical location, each production team had set grain quotas to meet. As communes were established, ownership of the means of production was emphasized as public. Not only were peasant secondary occupations banned, but also all production tools were given over to the state. Communes were entitled to the grain that production teams produced; this grain was distributed throughout the communes and served in common canteens.

The second Five-Year Plan initiated the Great Leap Forward. In 1958 advanced producers’ cooperatives merged to form communes, consisting of a number of production brigades and teams. These communes functioned as the primary form of government in the countryside. Leaders of production teams and brigades participated in local government affairs. Aside from the establishment of communes in the countryside, the central idea behind the Great Leap Forward was that rapid development of China’s agricultural and industrial sectors should take place simultaneously. Grain production and steel production were the keys to economic development at this time. But these two goals proved difficult to balance. The Great Leap Forward took its toll on the countryside when the combination of unrealistic grain production targets, the development of heavy industry, and climatic droughts led to widespread famine between 1959 and 1961. Urban residents, accessing food through ration coupons, faced the results of the famine with stricter rations but did not face famine to the extent faced by rural residents.

After the disaster of the Great Leap Forward the state loosened its control over the countryside. Farmers were given more freedom to grow and produce grain as they saw fit, although they continued to work in collectives and had to give grain output back to the state. In the mid- to late 1960s, as the Cultural Revolution (1966–1976) gained momentum throughout the cities and schools were shut down, a number of children of urban residents were “sent down” to the countryside to reform their thinking. Although they were supposed to begin to understand the lives of peasants, these students were kept in separate living and working quarters from the peasant households.

Reform Era

By 1978, two years after the death of Communist Party leader Mao Zedong, Deng Xiaoping had become leader of China. With this power shift much of the control over the rural collectives had been lost. In some places, particularly Anhui and Jiangsu provinces, farmers began to experiment with selling their grain surplus on the market and not directly to the state, beginning the household responsibility system (HRS). This system disassembled the communes and redistributed land to peasant households through contracts. HRS spread throughout the country by the early 1980s, initiating the period of reform and opening up. The years 1978–1984 are associated with massive rural reforms that broke apart the collective agricultural system and redistributed land from collective use rights to those of individual households.

Although the collectives remained owners of the land, the land was contracted out to the households. Brigade and team leaders divided lots of land up according to their size and productivity. Some households were given a variety of plots throughout the production team area that had differing degrees of size and productivity. Farmers were given incentive to work harder to increase the output from their plots. Each household was granted a procurement goal of grain production that needed to be handed over to the state. After households reached their goal (for which the state paid low grain prices), farmers were free to grow other crops or sell their surplus of grain on the market for a higher price.

Between 1978 and 1984 grain and other agricultural crop outputs rose dramatically. From 1980 to 1985 grain output grew at the rate of about 7 percent per year. Advances in technology, such as the introduction of high-yielding varieties of grain, additional farmer incentives, and the increased use of chemical fertilizers, also contributed to this upsurge in output. This initial dramatic rise in grain output compelled the state to continue economic reforms and, in 1985, shifted reforms to urban areas.
With attention turned to urban reform, the dramatic yield increase in the countryside could not be sustained. Yields stagnated in the mid-1980s. Farmers, whose incomes had grown with the rise in grain output, experienced loss of incomes and began to turn to cash and commercial crops. They began paying the state in taxes earned from the sale of these crops rather than grain. In the years since the initial success of the HRS, the state has focused much of its attention in rural areas on the development of township and village enterprises (TVEs).
Deng Xiaoping’s reform and opening up came the Four Modernizations. Deng believed that modernization was the key to China’s development and took great efforts to improve China’s agriculture, industry, defense, science, and technology. The Four Modernizations accelerated the pace of agricultural industrialization in China. When Deng Xiaoping introduced his plan to bring science and technology to China through modernization, the state invested significantly in agricultural technology. The state sent scientists abroad and brought foreign scientists to China to exchange ideas and information. The Ministries of Agriculture and Science and Technology began to develop modern agricultural technologies. Agricultural extension systems were set up throughout provincial and local governments to disperse new technologies and information.

State scientists designed technology to produce high yields of grain. Hybrid rice, developed and patented by Chinese scientist Yuan Longping, is especially important to China, given the cultural importance of rice as a staple crop. Much of the high quantities of rice produced in the 1980s was attributed to hybrid rice. More recently Chinese scientists have developed genetically engineered rice that is pest-resistant. The central government, however, afraid of trade repercussions with the European Union, has not yet fully commercialized this rice.

Another technology in which China holds an advantage is aquaculture. For centuries China relied on paddy fields, ponds, and canals to grow fish and other seafood products. Scientists have developed innovative techniques in recent years to improve China’s pond-raised fish, shrimp, crayfish, and eels. The combination of intensive human labor in aquaculture and the development of controlled ponds has given China a comparative advantage in aquaculture. When China entered the WTO, it found that possessing unique comparative advantages on certain agricultural techniques worked to its benefit.

**Modern Agricultural Technology**

Since 1978 Chinese agriculture has taken several large steps toward modernizing its agriculture. Along with as a way to curb migration to urban areas for industrial jobs. Also, China’s entry into the World Trade Organization (WTO) in 2001 has challenged the government to align its economy with the global economy. Domestic agricultural production faces the need to find its comparative advantage in the global economy. Experts expect that agriculture will continue to adapt to the challenges and opportunities that the global economy provides in the coming years.

**Food Security in a Changing Environment**

In 1995 Lester Brown, president of the Worldwatch Institute in Washington, D.C., asked a profound question that shaped the issues of food security in China. With the publication of *Who Will Feed China? Wake-Up Call*
for a Small Planet, Brown called attention to global food security by highlighting China’s environmental problems. His simplified claim was that the combination of industrialization and population would certainly affect not only China’s ability to feed itself but also the world’s food supply. In response to this book Chinese state scientists claim that hybrid and “super” rice technology will make it possible to feed the people of China. In the years since the book’s publication, many scientists have pointed out the flaws associated with the generalized claims that Brown made.

The legacy of the book, however, is the awareness it raised about the relationship between pressures of development and feeding China’s large society. The emphasis on grain production and self-sufficiency from the Mao era continues to guide policy. Yet China faces the need to develop and industrialize its economy. Moreover, the introduction of a consumer society in urban China also has the ability to affect grain production. In 2000 the Chinese government eliminated its price support for low-quality, early-season hybrid indica rice. This move drew attention because in the past the state had pushed farmers to grow double-season, high-yielding hybrid rice to prove China could be self-sufficient in grain production. By 2004, despite a drop in the quantity of rice produced in China, state agricultural officials initiated a campaign to promote “high-quality” grain. As China competes on a global scale, the importance of producing quality food products increasingly competes with the need to produce mass quantities of grain.

Growing Challenges

Chinese agricultural history is a complicated mix of political, economic, technological, and ecological opportunities and challenges. Many traditional practices of crop cultivation and technology continue in the twenty-first century. Many other practices have given way to modern forms of technology and economics. The large-scale political and social experimentation of agricultural collectivization in the 1950s through the 1970s provides an example of how the state had the power to organize society based on its own political ideals. The more recent introduction of the market economy and global integration have provided new opportunities and challenges for Chinese agriculture. With China’s entry into the WTO agricultural production has changed so China can compete in the global economy. At the same time, however, China faces the domestic needs of feeding its population, meeting the demands of a new consumer society, and protecting its fragile environmental resources.

China’s expansive and diverse geography has played a key role in shaping the agricultural practices and diets of the Chinese people. The study of agricultural geography (agro-geography) can reveal how various regional cuisines have emerged. As China’s physical and human environment alike undergo dramatic changes, the food and agriculture of Chinese people is likely to change as well.

Within the vast territory China encompasses, agricultural production takes many forms and is an integral industry. Whether it consists of large-scale, state-run soybean farms in the northeast, individual household plots of terraced rice paddies in the mountainous southwest, or vast expanses of grassland in the north and northwest, China’s agro-geography is certainly diverse.

The traditional, most simplistic characterization of China’s agro-geography is found within the ambiguous rice–wheat line that separates the dry northern areas of China from the southern wet regions where rice thrives. In the dry, cold north, sorghum and millet grow alongside soybeans and corn. The climate of areas along the Huang (Yellow) River is suitable for winter wheat. Traditional cuisines and food types have been constructed around these available grain products. For example, dumplings, noodles, and steamed buns made out of wheat flour form the basis of “northern” food, while the combination of dishes of meat or vegetables served with bowls of rice is considered “southern” cuisine. In the south, rice can be double-cropped in a single season due to abundant water and large tracts of cleared paddy land.

Over the past few decades, increased transportation, regional specialization, and agricultural technology have led to the blurring of this rice–wheat line. While rice remains the dominant staple crop in most southern areas, wheat and wheat products are widely available. At the same time, the northeast region of China has dramatically increased its production of short grain japonica rice. This short grain rice can sustain a shorter growing season and higher altitude than indica varieties grown in the south.

Today in China, regions highlight their own agricultural and food specialties as a way to define and distinguish themselves from other areas. For example, Beijing peaches, Shaanxi apples, and Xinjiang grapes are all commodities with regional identities. In addition to commodity fruits, specialty cuisines also claim an identity associated with a region. Although the food types and cuisines available in specific regions continues to diversify with modern transportation and the introduction of large supermarkets, regions—whether they are towns, cities, or provinces—highlight and advertise their specialties.

Regional Cuisine

In his classic work, The Food of China, E. N. Anderson breaks traditional cuisines into the following four loosely-defined categories: the east, the west (or southwest), the far south (Guangzhou—or Canton, as Anderson wrote
in 1988), and the north. East China, as defined by Anderson, consists of the lower Yangzi (Chang) Valley and the coasts north and south of it. Eastern cuisine— influenced by the abundance of fish and seafood in the area’s fresh and salt waters, as well as by the renowned vinegar produced in the region— gets its distinctive flavor from combinations of vinegar, oil, sugar, sweet bean paste, and rice ale. Soups and fish sauces are also important components in the cooking of this region (mainly Fujian).

Western China, commonly thought of as southwestern China at the other end of the Yangzi (Chang) River, is known for its spicy (Szechwan) food. Chile pepper, garlic, brown and black pepper, star anise, and five spice are found regularly in dishes in this region. Rich mountain forests in western Sichuan provide bamboo shoots and a variety of mushroom and fungi, which are often cooked with pork, tofu, and a variety of vegetables, usually accompanied by rice. While Chongqing municipality is known for its famous spicy fire pot (hot pot), minority regions in Sichuan, Yunnan, and Guizhou also have abundant local specialties.

The home of southern cooking in China— still popularly called Cantonese by those outside the country—is Guangzhou, the capital of Guangdong Province and a major city in mainland China with close ties to Hong Kong. Cantonese cuisine is known to be some of the best in China. Everyday dishes consist of simple boiled shrimp, steamed fish, stir-fried vegetables, clear soup, fried oysters, and boiled chicken. Luxury and gourmet offerings in Guangzhou feature meats uncommonly consumed in the rest of the world: shark fin, dog, cat, snake, turtle, and frog legs. Eating dim sum is a common form of snacking in south China. With its southern, semitropical location, southern China has famous fresh fruits.

The north of China is characterized by its taste for wheat products combined with mutton and other meats. Dumplings (jiaozi) and meat-filled stuffed steamed buns (baozi) are staples of this region. Muslim food from the

Flooded rice-paddy terraces are carved out of the hills and mountains all over southern China. The water prevents weeds and keeps the plants healthy and crop bountiful.

PHOTO BY JOAN LEBOLD COHEN.
northwest has made its way to northern China with its kabobs of spicy meat, as well as wheat breads and noodles.

**Agricultural Geography**

With the introduction of the household responsibility system and a market-based economy, agricultural production has become much more diversified in recent years. At the same time, agro-diversity has reached new regions, and agricultural production has become regionalized and specialized. The recent work of Gregory Veeck et al. (2007) divides China’s agro-diversity into nine distinct terrestrial agricultural regions and provides the most recent data from the nine regions. Veeck breaks down Chinese agriculture into nine regions: the Northeast, Inner Mongolia, East China Plain, the Loess Plateau, the Middle and Lower Reaches of the Yangzi River, the Southwest region, the South China region, the Gansu-Xinjiang region, and the Qinghai-Tibet region.

The northeast of China, generally referred to as Manchuria, includes the three provinces of Heilongjiang, Jilin, and Liaoning. The land is located primarily on the Songliao Plain and rimmed by mountains to the north, west, and east. As recently as the 1950s, this region was sparsely populated and heavily forested. Today, large portions of wetland and forest have been converted to agricultural land, and the northeast is one of China’s final agricultural frontiers. The region is rapidly gaining the reputation as a major grain producer in China, as most of the farms here are large-scale, state-run, mechanized, and grain-producing. Corn and soybeans have been the main crops grown here, but China’s recent entry into the WTO (World Trade Organization) has forced China to import these products. As a result, and with new technologies developed in China, the northeast has increased its rice production of short grain japonica rice dramatically over the past two decades.

Inner Mongolia is the dry and windswept area to the northwest of Beijing. Its land consists primarily of grasslands used for herding. During the Great Leap Forward and the Cultural Revolution, officials in this region made efforts to turn grasslands and pasturelands to field crop cultivation. Under Mao Zedong’s “Take Grain as the Key Link” campaign to increase grain production, grassland was converted to grain production. The results of this quick and poorly-planned initiative were disastrous, with 391,000 hectares of good pasture turned into desert. Today, more reasonable strategies are being applied to prevent massive environmental degradation, and recent years have brought an increase in the careful implementation of field crop cultivation. Wool and husbandry also act as major industries in this region, and are expected to continue to expand in the future.
The East China Plain includes the drainage basins of the Huang and Hai Rivers and their deltas. At the center of Chinese civilization in the heart of one of China’s most densely populated and productive agricultural regions, the East China Plain is currently facing a severe water shortage problem that is having a negative effect on grain production. Traditionally, land was double-cropped with the production of winter wheat, barley, and rapeseed, with summer crops of peanuts, corn, soybeans, and cotton. More recently, commercial and specialty fruits and vegetables that offer higher prices to farmers have been growing in popularity, as has cotton production.

The Loess Plateau, named for its thick deposits of silt, covers approximately 300,000 square kilometers of land in Gansu, Shanxi, and Shaanxi provinces. Although the loess is highly fertile, deforestation, drought, and sloping land have led to significant erosion in the region. Recent urban and industrial development has accelerated the pace of this erosion. Local governments have invested significant time and money in efforts to stabilize agricultural production of this region. The most recent endeavor has been the promotion of fruit with the growth of apple orchards.

The middle and lower reaches of the Yangzi River are at the agricultural core of China. The mild climate and high rainfall throughout this region allow for double cropping of winter wheat and barley, rapeseed, and rice. In terms of grain production, the region boasts the highest annual mean yields throughout the country. However, industrialization and the pressures of development have forced many rural areas of agricultural production to be converted to industrialization. In recent years, vegetable, flower, and fruit production has increased dramatically, with ample opportunity for processing and exporting.

Southwest China includes two major geographical features: the highly fertile cropland of the Sichuan Basin and the high, rocky, sloped mountain terrain of the Yunnan-Guizhou Plateau. The Sichuan Basin produces much of China’s grain, including rice and corn, with high swine production rates as well. Its inland location allows this basin to avoid price influences from imported grain. In contrast, the rugged karst topography of the Yunnan-Guizhou Plateau has a poorly developed agricultural sector. The region lacks sufficient roads to transport agricultural products. Even with high production of citrus and other fruits, transportation is a problem and the industry is facing competition from southern China and Southeast Asia. Yunnan Province is China’s major source of tobacco.

The South China Region consists primarily of low mountains and hills. It encompasses the major (fertile) alluvial plains from the Pearl River Delta and the West
River. Its southern, moist location allows for double cropping of rice and, on occasion, a season of winter wheat. Mulberry production for silkworms and tea remain important non-grain crops. Sugarcane aquacultural products, tropical fruits, and spices are also major products of the region. The Pearl River Delta was, for centuries, one of China’s most important and productive agricultural regions. Today, however, due to its close proximity to Hong Kong, the region’s agricultural land is threatened by encroaching industrial and urban development.

The Gansu-Xinjiang region makes up one of the largest, driest, and least-populated areas of China. On average, it receives less than 200 millimeters of rainfall per year. Irrigation systems are fed through snowmelt of the surrounding mountain chains. In recent years, grapes, melons, dates, and other specialty crops have gained popularity throughout China. More recently, the introduction of irrigated cotton and sugar beets has presented competition with these products. Traditional practices of herding sheep, goats, camels, and horses continue in remote and nonirrigated areas. New drought-resistant grain crops have been introduced.

The Qinghai-Tibet region is on the high Tibetan Plateau (over 4,500 meters in height). The region is cold and dry. Much of the food purchased here has been brought from other areas of China. Sheep, yak, and horse herding remain an integral part of the economy. In valleys, wheat and barley are grown, as are potatoes and other vegetables. Greenhouses have been built in efforts to improve local food supplies, but in general, this region lacks fresh fruit and vegetables.

Future Directions

As China dives deeper into the twenty-first century, its agricultural production relies upon a variety of social and environmental issues. The opportunities and challenges of these issues can be understood primarily through the following four categories: water and other resource issues, industrial and urban development, farming as a livelihood, and the impact of international trade.

Water issues are a large problem in China. Climatic conditions in China vary from dry deserts in the north, to mountains in the west, to wet paddy fields in the south. Access to water has been a key factor in the growth of agricultural systems. For thousands of years Chinese leaders have manipulated water through complex irrigation systems to ensure agricultural growth. With the Three Gorges Dam and proposed South–North Water Transfer Project, the state continues to control the flow of water. As parts of north China face droughts, soil erosion, and desertification, southern China faces devastating floods. The technological solutions have ecological
and social implications that many believe the government has not effectively considered before starting the projects. As the government relies on regions of China for food production, access to water is a challenge that must be addressed.

A continuous theme that has come up in the discussion of regional variations in agriculture is the impending industrial development in certain regions of China. For example, the southeast of China boasts optimal land, soil, and climate for multiple grain crops within a single season. But this region is also China’s most rapidly growing industrial region. Hectares of agricultural land are converted to industry and suburban residential development. As a result, local governments in regions not known for optimum growing conditions are advocating the development of crop production. Having learned from mistakes of pushing the land to produce too much under Mao, these programs rely on scientific advice and technology.

Farming as a livelihood has always been of particular concern to the Chinese government. Recently, as economic reforms have favored urban residents, farmers have begun to show their distrust of and uncertainty about the government through protests and other forms of discontent. As a result, the government has instituted a series of plans meant to bring peace to the Chinese countryside through constructing a “harmonious society.” This policy, associated with the Hu Jintao leadership, acknowledges the new problems that have emerged with China’s economic growth. Tensions are rising due to increased inequality, environmental damage, health problems, and attempts to break the social pension plan known as the “iron rice bowl” that began in the Mao era. The new policy seeks to address these issues in the rural countryside.

Increased international trade resulting from China’s entry into the WTO is expected to have long-term effects. After a long struggle with the United States, China finally joined the WTO in 2001. The immediate effects of the union can be seen in the price decreases of domestic soybeans and corn. At the same time, prices of California produce such as garlic and fruit have declined as a result of the growth of Chinese exports. It is expected that similar economic issues will arise in the future as the path China takes in agricultural trade becomes more paved. Different regions in China may have to take advantage of new demands, resulting in changing social and ecological conditions.

Implications

Over the past century, changes in food production and consumption in China have affected regional specialized cuisines. However, as a result of the introduction of new agricultural products, regions are recognizing the threat of losing traditional cuisines and are marketing and promoting the agricultural and culinary specialties of their area through local restaurants or tourism industries. As regions promote certain foods and products, agricultural production has become regionalized and specialized in recent years. While grain production continues to be encouraged by the state, it is no longer the case that all farmers must produce grain. A variety of social and ecological conditions both inhibit and encourage the development of new crop specializations. It appears as though government officials and researchers are much more careful about how to implement these programs. With the growth of supermarkets, increased transportation, and interaction with the global economy, food and agriculture in China will continue to shift spatial locations.

American Chamber of Commerce in China

Zhōngguó-Měiguó Shānghuì 中国美国商会

The American Chamber of Commerce in the People’s Republic of China (AmCham-China) helps U.S. companies succeed in China through information, networking, and business support services.

The American Chamber of Commerce in the People’s Republic of China (AmCham-China) is a nonprofit organization that represents U.S. companies and individuals doing business in China. The first office opened in Beijing in 1980. With the American Chamber of Commerce in Shanghai and the American Chamber of Commerce in South China, AmCham-China represents seven thousand companies. It is part of the larger Association of American Chambers of Commerce, which represents more than 3 million companies worldwide.

The chamber has more than forty industry- and issue-specific forums and committees, offers services such as the Business Visa Program, holds a range of networking and informational events, and meets with U.S and Chinese officials to discuss challenges and opportunities facing U.S. firms doing business in China.

The chamber’s mission is to help U.S. companies succeed in China through advocacy, information, networking, and business support services. The objectives of the chamber are to:

- promote the development of trade, commerce, and investment between the United States and China;
- provide a forum in which the U.S. business community in China can identify and discuss common commercial interests in China;
- work with existing organizations in China on matters of mutual interest;
- maintain relations with the Chamber of Commerce of the United States and other chambers of commerce or commercial organizations elsewhere.

As one of Taiwan’s aboriginal tribes, the Ami continue to live together in villages and practice their ancient customs and rituals. The most significant of their traditional celebrations, commonly known as the Harvest Festival, is still held annually throughout Taiwan.

The Ami is the largest of the nine tribes of indigenous people on Taiwan, numbering approximately 158,000 in 2007, according to statistics from Taiwan’s Council of Indigenous Peoples. They were known to the Chinese settlers as “the mountain people” because they retreated to the mountainous center of Taiwan when large numbers of Chinese immigrated in the seventeenth century. They still live primarily in the hilly area in the southeastern part of Taiwan and along the east coast. Many Ami are fishermen, but their main source of income comes from agricultural products such as rice, millet, sweet potatoes, seedless watermelons, sugar cane, mulberry leaves, tea, and tobacco.

The Ami people are organized into villages headed by a chief, and the family structure is matrilineal, meaning that the women own property, and the eldest daughter inherits the family property. Recent research, however, focuses on other important social organizations such as the household and age-set systems. In many indigenous cultures young men who are initiated at the same time through rites of passage into adulthood are grouped into age sets, each of which will eventually enjoy increasing power and respect as it approaches elder status. Age-set organizations are common to all traditional Ami tribes.

The religious beliefs and activities of the Ami revolve around divine spirits, divination, and ancestor worship. Rituals and traditions continue to play a significant role in the Ami culture. The largest and most important ceremony is the annual millet harvest festival, also known as the “Good Year” Festival. Just like Chinese and Western New Year celebrations, this is a time for families and friends to gather together and reinforce both personal and divine relationships. Each village decides for itself when the Harvest Festival starts, usually in late August or early September, and how long it lasts, usually between

one and seven days. Tribal officials announce the dates at least a month in advance; because it marks the end of one growing season and the coming of another, the festival starts at night.

The festival is a time in which the rigorous organization of the age-set system in Ami culture is still apparent. Women are not allowed to participate in the festival on the first day, but they play an important part in the closing ceremonies. The villagers dress in colorful traditional attire and sing and dance in honor of the spirits; rice and homemade wines are served. Sports and symbolic open-sea fishing are also observed as part of the festivities. The biggest festival is held in Hualien, the largest town on the east coast. It has become one of Taiwan’s main tourist attractions.

An Lushan (An Shi) Rebellion

An-Shi Zhi Luân 安史之乱

The An Lushan Rebellion (755–763 CE) was an uprising against the Tang dynasty by a rapid succession of four rebel emperors of mixed Turkic-Sogdian ethnicity, whose ancestors came from present-day Uzbekistan. The event generated a rich cultural heritage recounting the devastation of the country, and it romanticized the folly of Emperor Xuanzong and his beloved imperial concubine Yang.

On 16 December 755 CE, An Lushan (703–757), or Rokshan (Persian for “light”), swept south from Fanyang (today’s Beijing region) with a multiethnic army of 150,000–200,000 troops (Xi, Malgal, Tongra, Khitan, and Chinese) and mounted a catastrophic rebellion against Tang dynasty China (618–907) in the name of a new dynasty, Yan. In the next seven years the Tang capitals of Chang’an and Luoyang were occupied by a rapid succession of four rebel emperors of mixed Turkic-Sogdian ethnicity (An Lushan and his son An Qingxu and Shi Siming and his son Shi Chaoyi), whose ancestors came from present-day Uzbekistan and spoke a Persian (Iranian) language. The An Lushan Rebellion was more than a significant military event in Tang China; in literary and artistic circles it generated a rich cultural heritage that recounted the devastation of the country and romanticized the tragedy and folly of Emperor Xuanzong (reigned 712–756) and his beloved imperial concubine Yang (719–756), who had formerly been the wife of one of his sons.

This tomb figure of a warrior, in pottery painted with color and gold, from the end of the seventh century (Tang dynasty) is in the collection of the Historical Museum, Xi’an, Shaanxi Province. The features of this Tang warrior’s face suggest that he was descended at least partially from Central Asian forebears; military armor such as this figure wears was in use at the time of the An Lushan Rebellion. Photo by Joan Lebold Cohen.
Chinese primary and secondary sources vilify An Lushan as a semi-sinicized military governor of three strategic provinces in the northeast (Pinglu, Fanyang, and Hebei) whose rebellion brought widespread famine and deaths by the millions. The narrative is focused on the palace spectacle, where the obese and exotic-looking An Lushan had first convinced Emperor Xuanzong of his loyalty to the Tang throne through over a decade of frontier defense against the border peoples. When summoned to the Tang court, An Lushan entertained the women of the court while dressed as a baby and was adopted as a son by the imperial concubine Yang. Her cousin, Prime Minister Yang Guozhong, repeatedly warned that An Lushan harbored a seditious intent, and indeed An Lushan rebelled, and his forces quickly cut off access to the Grand Canal, the economic lifeline that connected the economies of the north and the south. The rebellion drove Emperor Xuanzong and his entourage to seek refuge in Sichuan, but at the Mawei postal station his soldiers executed Yang Guozhong and forced the suicide of the imperial concubine Yang, whom they blamed for provoking An Lushan and plunging the country into civil war. Xuanzong abdicated in favor of his son Suzong (reigned 756–762), who enlisted the assistance of the Uighur cavalry to crush the rebels. Both emperors died before the rebellion came to a conclusion in January 763, when the
much-diminished Tang dynasty allowed the rebel generals, previously connected with An Lushan, to retain their military governorships in the northeast.

**Origins of the Rebellion**

Scholarship in the West has produced translations of An Lushan’s biography in the official histories and probed deeper into the political and military developments that led to the rebellion. A patron of the arts and literature, Emperor Xuanzong has been credited with Tang’s golden age of peace and prosperity at home and abroad until the rebellion occurred. He is blamed for supporting his prime minister, Li Linfu (d. 752), whose political and military reforms in 736–752 weakened the central government and gave rise to regionalism and separatism in the northeast provinces, the base for An Lushan’s operations. In 749 Li dealt a death blow to the cost-effective *fubing* (garrison soldiery) system of soldier-cultivators, in which soldiers farmed the land in the growing season and at other times undertook military exercises and tours of duty at the capitals and the frontiers. Expenditures were kept low as the soldier-cultivators provided for their own food, equipment, and horses in return for larger land allocations and exemption from taxes and unpaid public labor. The garrison soldiery system was totally replaced by a professional army, accounting for the largest single expenditure of the central government because salaries, food, and equipment were now state expenses. Eighty-five percent of these career soldiers were placed under military governors, who had large staffs and generous funds to direct the loyalty of their soldiers to themselves rather than to the Tang throne. Contrary to the tradition of selecting military governors from the aristocracy and bureaucracy, Li Linfu appointed non-Chinese career military officers to the frontier provinces to carry out an aggressive and precarious foreign policy. In 751 Gao Xianzhi, a Tang general of Korean ancestry, lost the Battle of Talas (in Kyrgyzstan) to the Arabs, after which Tang China relinquished control over Tashkent and Ferghana in central Asia. An Lushan and Shi Siming, career military men from the Turkic-Sogdian disporic communities in Beijing, benefited enormously from Li Linfu’s military policies and exploited the discontent of the northeast population against the Tang dynasty’s discriminatory measures. The military governors were in charge of the civil and military administration, and as they increased the size of their armies, their provinces also became new centers of trade. Rebellion was ripe in the northeast provinces, which had a direct invasion route to Luoyang and were located closer than the Tang capitals to the rich south.

**Outcome of the Rebellion**

The Tibetans and Uighurs were the winners in the rebellion. The Tibetans saw the opportunity to dominate the provinces of Gansu and Ningxia when the Tang
government withdrew frontier troops to defend the capitals. In 760 the Tibetan king, Trisong Detsen (reigned 755–797), invaded Sichuan Province and exacted annual payments of silk from Tang China; in late 763 he charged into Chang’an and installed a pretender to the Tang throne. The Uighurs, who had earlier assisted the Tang dynasty with troops and horses to crush the rebel forces, now drove the Tibetans out and were paid with princess brides and a lucrative horse trade.

The Tang dynasty survived the rebellion but never recovered its external prestige and internal stability. The central government accepted the autonomy of the northeast provinces and lost 25 to 30 percent of the tax base. The financial structure of the dynasty had collapsed during the rebellion, and the taxation system had to be overhauled by 780, when the poll tax in kind (grain, cloth, corvee [labor]), based on the number of people in the household, was replaced with a twice-yearly tax payable in cash. The southward shift of population from the war-torn northeast to the Huai and Yangzi regions gave new importance to the central and southern parts of the country as the chief source of revenue for the central government.

The rebellion was a turning point in the history of Tang China in that the dynasty never recovered its strength and prestige, and the dynasty survived only with drastic changes to the provincial administration and tax systems.

The Analects, containing the sayings of the philosopher Confucius and his followers, is one of the most influential texts in Chinese philosophy. Until 1905 mastery of the Analects was required for the imperial civil service examination.

The sayings of the Chinese philosopher Confucius (551–479 BCE) and his disciples are recorded in the Analects, a text that influenced government service and education in China, Korea, Vietnam, and Japan for more than two thousand years.

The Analects (Chinese Lunyu) is one of the most influential texts in Chinese philosophy. The disciples of Confucius and their followers compiled it, although historians debate exactly when, as shown by the following opinions of Confucian scholars. D. C. Lau maintains the traditional view that the first fifteen books were written shortly after Confucius’s death and that the remaining five books were written by the second generation of disciples. John Makeham argues that the changing textual material did not settle into its present form until 150 BCE, while A. Taeko Brooks and E. Bruce Brooks suggest that books 4 through 11 are the oldest, that books 9 through 11 were written by second-generation disciples, and what remains was written at different times. By 55 BCE the Analects was basically in its present form, the fragments excavated at Dingzhou indicate.

The Analects is the first of the so-called Four Books, the Confucian texts whose mastery was required for imperial civil service examinations until they were abolished in 1905. The Four Books are the Analects, the Men-tius, the Great Learning, and Centrality and Commonality, which is often mistranslated as the Golden Mean.

The Analects is made up of brief statements attributed mostly to Confucius; some are attributed to his disciples or to rulers. Modern readers generally are struck by the brevity of the statements and by the apparent lack of sustained prose or argument, which may well have been Confucius’s method of teaching. He expected his students to be eager to learn: He gave them only one corner of the square, and if they did not return with the other three corners, he would not review their lesson (Analects 7:8).

The general goal of the text is to guide the reader in self-cultivation so that the reader can become a moral example for others. For example, a reader might find the proper way to live and behave by practicing various virtues (de), thereby becoming a humane person (ren zhe) or a prince of virtue (junzi, usually translated as “gentleman”). In the Analects humanity or benevolence (ren) is the most important virtue; it is mentioned more than one hundred times. Ren is an achievement concept: A person is not born humane but rather must learn to become humane. Ren means to love others (Analects 12:22). The best way to express human kindness is the practice of ritual action (li). Ritual action is not restricted to state and religious functions but rather covers the spectrum of human behavior. Pragmatically speaking, children first must learn filial piety (xiao) and brotherly love (di) at home; then, as they grow up, they can extend their family love to others in the form of ren.
Confucius stressed literacy, study, and learning to develop moral wisdom. Rote memorization is not sufficient; one also must be thoughtful. He also expected his disciples to be loyal and to do what was proper, especially in government service. When the disciple Zigong asked if there is a single word that a person can use as guidance, Confucius replied that perhaps it would be empathy (shu): to “never do to another what you do not desire” (Analects 15:24, 12:2).

Ancestor Worship

Jìdiàn zǔxiān 祭奠祖先

Devotees of nearly every religious tradition in China participate in ancestor worship, the rituals in which one commemorates, communicates with, or makes sacrifices to one’s deceased relatives. It is among the oldest and most enduring of Chinese religious practices.

Ancestor worship is the ritualized commemoration of, communication with, and sacrifice to one’s deceased relations. Even though the cult of ancestors frequently has been described as Confucian, devotees of nearly every religious tradition in China practice ancestor worship. Indeed, it is among the oldest and most enduring of Chinese religious practices, and whether Chinese participate in ancestor worship may function as an indicator of their “Chinese-ness.” For this reason Chinese Muslims and Christians, who historically have eschewed ancestor worship on doctrinal grounds, sometimes have faced questions about the authenticity of their ethnic or national identities.

Through the influence of Confucianism on China’s neighboring cultures, Chinese norms for venerating deceased kin have spread across east Asia. In spite of repressions of traditional religious activity in mainland China and forceful trends toward modernization and secularization throughout east Asia, ancestor worship remains a vital component of community life in China, its surrounding region, and throughout the worldwide Chinese diaspora.

Early History

The earliest known Chinese writings document the practice of ancestor worship among the rulers of the Shang dynasty (1766–1045 BCE). Shang court diviners used oracle bones (jiǎgǔ), cattle scapulas, and turtle plastrons...
heated over a fire to pose questions to Shang royal ancestors, to whom they erected temples and offered sacrifices. Shang ancestor cult and Shang divination shared a common purpose: to maintain harmonious relations between this world and the next for the benefit of the human community. The questions or charges (mingci) inscribed on oracle bones were formulated as possible outcomes of a current situation: “In the next ten days, there will perhaps be no disasters.” “Today it will not rain.” Some charges concern the ancestor worship itself: “On the next day, we should not make offering to Ancestor Yi.” Shang diviners and their royal patrons seem to have believed that ancestors, as former human beings, maintained some interest in mortal affairs and that they were more approachable, intelligible, and consistent than other supernatural agents—such as deities of natural forces or entities, or Shang Di, the “High God,” who may have been an amalgamation of long-deceased kings—who were more remote, mysterious, and capricious. Even so, the content of Shang charges indicates that the ancestors were blamed for misfortune as well as credited with blessings.

Both sacrifices to and consultations of ancestral spirits were coordinated according to a bureaucratic calendar regulated by the state. It is unknown whether Shang commoners consulted their deceased kin or otherwise participated in ancestor worship, but the ubiquity of the practice in almost all later Chinese cultural history suggests that they did. What is clear is the powerful and persistent link between two perennial Chinese religious concerns, the relationship of the living with the dead (ancestor worship), and the significance of the past and present for the future (divination). Shang ancestor worship also unified for the first time what would become two important strands of Chinese religious life: kinship hierarchy and

state bureaucracy. As the Shang lost power to the Zhou dynasty (1045–256 BCE), royal divination and sacrifice to royal ancestors continued, but increasingly divination on behalf of the ruler became decoupled from the ancestors and linked to more impersonal cosmic processes. By the late Warring States period (475–221 BCE), Chinese discourse about divination tended to focus on cosmological forces such as yin (dark, female, moist, receptive energies) and yang (lucid, male, arid, active energies), the moral qualities of the diviner, or both. Yet ancestor worship remained a vital part of Chinese life.

Confucian Perspectives

While adherents of nearly every Chinese religious movement or philosophical school during Warring States seem to have practiced ancestor worship, the Confucians made it the focal point of their moral and spiritual message. The Confucian anthology known as the Lunyu (Analects) records several sayings of Confucius (Kongzi, c. 551–479 BCE) on the importance of reverence (jing) for one’s ancestors: “Observe what a person has in mind to do when his father is alive, and then observe what he does when his father is dead. If, for three years, he makes no changes to his father’s ways, he can be said to be a good son” (Analects 1:11). Subsequent Confucian texts all refer to ancestor worship approvingly and commend it as a means of cultivating the virtue of filial piety (xiao) as well as instilling harmonious relations in society. It is not always clear whether classical Confucian authors maintain belief in the supernatural existence or power of ancestors, but their reverence for ancestor worship as a core element in the spiritual life is unambiguous.

With the rise of the Han dynasty (206 BCE–220 CE), which soon endorsed Confucianism as its official ideology, ancestor worship was incorporated into the systematic thought of the period, which both embraced cosmological notions about yin and yang and tended to project the bureaucratic structure of this world onto the next. Accordingly, human beings were thought to possess two distinct souls or spiritual essences. One, the hun, was identified with yang; light, ethereal, and intellectual, it was said to ascend and become an ancestor (zu) at death. By contrast, one’s po soul—dark, gravid, and sensual—was supposed to remain with the entombed corpse and become a ghost (gui). Rites for the dead then became ways in which to guarantee that the deceased’s hun and po separated properly and reached their appointed destinations. If family members displeased the dead or performed funerary rituals inadequately, they risked prompting the gui to leave the grave and wander, wreaking havoc on the living. Conversely, the failure to maintain reverence through ancestor worship could inspire the zu to abandon its advocacy for the living within the complex celestial bureaucracy envisioned by Han writings.

Archaeological and art-historical evidence suggests that, by the end of the Han dynasty, persons at nearly
all levels of Chinese society regularly worshipped their ancestors. The goal of ancestor worship became ensuring that one’s dead relations did indeed become ancestors, rather than ghosts: supernatural powers that were benevolent and remote, rather than malevolent and proximate. On this point it is important to note that, beginning with Han texts, ancestors can be described as *shen* (spirits), a term that also means “gods.” Indeed, the boundary between ancestors and deities is fluid, such that some ancestors became gods over time through promotion within the celestial bureaucracy.

**Buddhist Contributions**

Along with the ideas of afterlife and goals of ancestor ritual, these Han-era concepts represent all but one important element in subsequent Chinese ancestor worship. That final element was contributed by Buddhism, which was introduced to China sometime around the middle of the Han dynasty. Emerging from a quite different religious milieu than that of ancient China, Buddhism brought the notion of karmic retribution— whereby one’s deeds, or misdeeds, conditioned the quality of one’s rebirths in a cyclical existence—to the many Chinese who were disenchanted with Confucianism as its fortunes faded with the collapse of the Han dynasty in the third century. Chinese converts to Buddhism who took monastic vows were accused of betraying their families and abandoning their ritual obligations to ancestors. Citing the doctrine of karma, many responded by arguing that their entrance into monastic life could only benefit their families and honor their ancestors by bringing karmic merit to both. As Buddhism wove itself into the fabric
of Chinese culture, this argument proved persuasive to all but the most doctrinaire Confucians. And as sectarian Daoist movements proliferated between the Han and Tang (618–907 CE) dynasties, these too presented their rites and institutions as ways of serving the ancestors, even as they also catered to quite personal concerns, such as individual immortality.

Despite the widespread practice of ancestor worship in ancient and medieval China, formalized ancestor cult was confined largely to the ruling classes through the Tang dynasty. It was not until the Confucian revival of the Song dynasty (960–1279) that elite practices, such as detailed genealogical record keeping and the construction of temples dedicated solely to ancestor worship, became part of everyday life for commoners.

**Observance for All**

Song emperors, who relied upon Confucian scholars to help stabilize and legitimize their regime, listened when Confucian thinkers such as Cheng Yi (1033–1107) advocated genealogical research and ancestral temples for nonelites. Later Confucian reformers, such as Zhu Xi (1130–1200), devised ritual manuals that helped formalize and popularize ancestor worship among the lower classes. By the end of the Southern Song period (1127–1279), ancestor worship according to canonical Confucian procedures could be found at nearly all levels of Chinese society. As the Song regime lost prestige and territory to non-Chinese powers—such as the Jurchen peoples, who overthrew Song rule in northern China in 1127, or the Mongols, who defeated the final Song emperor’s forces in 1279 and ruled China as the Yuan dynasty until 1368—ancestor worship became one way in which to bolster Chinese ethnic and national self-confidence.

**Current Role**

The unprecedented creation and distribution of wealth during the Song prompted the development of a new role for ancestor worship: safeguarding property claims. Detailed genealogies furnished the basis of a family’s ancestral rolls. These could, in turn, be used to certify a family’s claim to estates or trade monopolies. Thus, at the dawn of the modern era, as China became one of the world’s most prosperous nations, ancestor worship and its related practices proved crucial for the maintenance and transmission of prosperity.

By the late imperial period (from the founding of the Ming dynasty in 1368 to the fall of the Qing dynasty in 1912), ancestor worship had attained the form in which it is found today. Using genealogical records kept by senior members, families memorialize deceased kin using name plaques or tablets placed on home altars or in family temples. In some rural villages, in which most residents share a common family name, the primary venue of ancestor worship may be a public temple. Offerings of incense, cooked rice, or fresh fruit are made to ancestors who remain within living memory, usually only those of the last two or three generations. Popular understandings suggest that, much like the deceased kings consulted by Shang royal diviners, the power and willingness of ancestors to assist the living declines as the generational gap between them widens. Over time, as ancestors recede from the consciousness of the living, their name plaques or tablets are ritually burned.

**Important Festivals**

While ancestor worship may take place daily, the two occasions in the Chinese ritual year in which it is most prominent are the Ghost-Feeding Festival (Zhongyuanjie or Yulanpen), which is celebrated in late summer, and the Clear and Bright Festival (Qingmingjie), which is celebrated in early spring. Zhongyuanjie is observed on the thirteenth day of the seventh lunar month, which in turn is known as Ghost Month (Guiyue) because it is at this time that the spirits of the dead are supposed to wander the earth. Both Buddhist and Daoist elements are prominent in the celebration of this festival, which commemorates the rescue of a suffering mother in an undesirable realm of rebirth by her filial son. In addition to Buddhist and Daoist liturgies for the relief of ancestors suffering in their rebirths, Zhongyuanjie features the offering of items such as paper houses, clothing, consumer commodities, and elaborate meals to the ancestors. During Qingmingjie, popularly known as Tomb-Sweeping Day, families visit and clean their ancestors’ burial places, conduct worship services, and share festive meals. Thus
during Zhongyuanjie the dead visit the living, and during Qingmingjie the living seek out the dead.

A Lasting Practice

Like other emblems of traditional Chinese religious life, ancestor worship was the target of severe criticism and persecution when Communist leader Mao Zedong (1893–1976) was in power. During the Cultural Revolution (1966–1976), in particular, popular domestic rituals, such as ancestor worship, were suppressed by the state, and community venues for ancestor worship, such as village temples, were destroyed or used for secular purposes. The traditional practice of burying one’s dead was condemned in favor of cremation. Cemeteries were converted to agricultural uses. Zealous young students supervised the burning of home altars and ancestral tablets.

The death of Mao relaxed, but did not end, government censure of ancestor worship. The Eleventh Party Congress of 1979 proclaimed that, although “certain long-standing activities such as ancestor worship” were “a kind of superstition,” henceforth they would not be proscribed “as long as they do not affect collective political and economic activities,” and that the government placed its faith in “patient persuasion and lasting education in science, culture, and atheism” to root out such practices eventually.

Since the 1980s, both public and private ancestor worship have become more prominent in mainland China, and these practices have remained strong in Hong Kong and Taiwan, as well as in overseas Chinese communities.

Anhui Province

Anhui is a small, land-locked province in eastern China about the size of the state of North Carolina. The province boasts a rich cultural history; many of China’s most important ancient philosophers and several types of traditional Chinese opera were born there.

Anhui was officially established as a province in 1667 during the Qing dynasty (1644–1912). The word “Anhui” is a portmanteau word derived from the Anqing and Huizhou prefectures. With Hefei as its capital city (with an estimated 2007 population of 4.79 million), Anhui Province has fifty-six counties with a total area of about 139,000 square kilometers (approximately the size of the state of North Carolina). It borders on Henan, Shandong, Jiangsu, Zhejiang, Jiangxi, and Hubei provinces, and lies in the middle and lower valleys of the Yangzi (Chang) and Huai rivers.

Anhui is one of the more important agricultural provinces in China, with products ranging from rice, wheat, cotton, vegetable oil crops, tea, and silkworm cocoons. Its gross domestic product (GDP) for 2007 was 734.57 billion yuan, up 13.9 percent from the previous year, and per capital GDP reached 12,015 yuan.

Its population includes several ethnic minority groups: Hui, She, Manchu, Zhuang, and Miao. Han Chinese make up the vast majority of the population in the province; the She and Hui ethnic groups are the two largest minorities.

Anhui abounds in natural resources, with large mineral deposits of coal, iron ore, and copper ore. With two major rivers—the Huai River in the north and the Yangzi (Chang) River in the south, running through the

View of Huangshan (Mount Huang) in Anhui Province. Photo by Joan Lebold Cohen.
province from west to east, Anhui is divided into three regions: Huaibei (north of Huai River), Jianghuai (between the two rivers), and Jiangnan (south of the Yangzi River). Lake Chaohu, in the center of the province, with an area of about 800 square kilometers, is one of the five largest freshwater lakes in China, although like many of China’s lakes it suffers from heavy pollution. Many lakes also cover the southeastern part of the province near the Yangzi River. The province enjoys a warm temperate, semi-humid monsoon climate, with annual temperatures averaging between 14–17 degrees centigrade. Annual rainfall ranges from about 800 to 1,800 millimeters.

In 1990, Huangshan (Mount Huang), known to poets and painters through history as one of the loveliest mountains in China, was added to the United Nations Educational, Scientific, and Cultural Organization’s
Anhui Province (UNESCO) World Heritage List (a list that seeks to identify, protect, and preserve examples of cultural and natural heritage around the world). In addition, two traditional villages of Yi County (Xidi and Hongcun) in Anhui Province were also added as cultural properties in 2000.

Historically, Anhui is the birthplace of much of China’s ancient culture, and it remained an important part of China’s cultural development for centuries. Scientists have discovered a historical site in Fanmao County where human activities more than 2 million years old can be traced. Moreover, along the Huai River basin, many philosophers, such as Laozi (credited as the founder of Daoism), Zhuang Zi, and Guan Zhong were born; their philosophies influenced more than 2,000 years of Chinese history. Operas in several forms have been developed in the province.

Anhui has a high concentration of traditional products related to calligraphy: Xuanzhou (today Xuancheng) and Huizhou (today Huangshan City) are revered for producing xuan paper (often called rice paper, but actually handmade from bark) and hui ink, respectively, which are traditionally considered the best types of paper and ink for Chinese calligraphy. She County is famous for the She Inkstone, one of the most preferred types of inkstones (a mortar-like stone used for grinding and holding ink) in the world.

Antidrug Campaigns

Dàguǐmó sàngǔ yùndòng 大规模扫毒运动

Chinese regimes from the Qing (1644–1912) to the People’s Republic have struggled to control problems with drugs, most notably opium, a particularly complex issue intertwined with Chinese politics and perceptions of the nation’s social and economic health and advancement. Despite campaigns against opium, eliminating it has proved as elusive for China as it has for most of the rest of the world.

For more than a century, between the end of the First Opium War in 1842 and the founding of the People’s Republic of China in 1949, China’s name was virtually synonymous with drug problems, particularly those related to the consumption, cultivation, and sale of opium. Opium not only was considered a problem in terms of widespread addiction and impoverishment but also became a powerful symbol of all that was ailing the “sick man of Asia”: By the mid-nineteenth century the Qing dynasty (1644–1912) was wracked by internal rebellions, beset by the demands of aggressive imperialist powers, and weakened by severe financial strains.

The passivity of the seemingly stereotypical Chinese opium smoker seemed an apt metaphor for the backwardness of the traditional imperial system and its alleged inability to shake itself out of its stupor. However, the reality was quite different. Most Chinese opium smokers were not emaciated, lethargic addicts, and the Chinese state made numerous attempts to eliminate what it saw as the problem of opium, launching several nationwide suppression campaigns that achieved varying degrees of success.

China’s relationship with opium is lengthy and complex. Chinese had long valued the drug for its myriad medical and sexual benefits and even for the beauty of the poppy flower. By the mid-Qing dynasty, however, China’s rulers began to worry about the impact of the drug on the elite class. China’s first anti-opium edict in 1729 struck at opium dealers and the proprietors of opium dens. Opium imports were forbidden in 1796, but the number of chests steadily increased to meet the growing Chinese demand. Two hundred chests of foreign opium (at around 61 kilograms per chest) were imported in 1729, but by 1838, on the eve of the First Opium War (1839–1842), that number had increased a hundredfold.

Early Efforts

Since the mid-nineteenth century the Chinese government has conducted four noteworthy anti-opium campaigns, initiated by each of China’s three major regimes. The first campaign, led by Lin Zexu (1785–1850), China’s most famous anti-opium activist, was largely confined to the port city of Guangzhou (Canton) immediately before the outbreak of the First Opium War. The clandestine drug trade had proven so lucrative for foreign merchants that it generated a heated debate at the highest levels of the Qing court in 1836. Several high officials pushed to legalize the drug so that the state could profit in the short
term while gaining a degree of control that would eventually allow it to eliminate the trade. Others opposed the drug trade not only because it was illegal but also because opium’s addictive nature harmed individual health and social stability.

Ultimately, the state committed itself to prohibition and named Lin Zexu imperial commissioner with the authority to eliminate China’s opium problem. The 1839 anti-opium campaign focused on Guangzhou, where the geographical isolation of China’s foreign trade under the Canton system meant an especially acute opium problem that represented a galling affront to Qing law and sovereignty. Lin paired an educational initiative with the registration and treatment of smokers, the recruitment of a network of informants to discourage smugglers, and harsh restrictions that made smoking a capital offense in certain circumstances. Even more dramatically, he demanded that foreign merchants hand over more than twenty thousand chests of opium and blockaded the merchants in their warehouses until they complied. Lin then destroyed the drug, infuriating the British and setting the stage for the First Opium War.

China’s loss in the First Opium War brought outrage and humiliation to the Chinese, but the opium trade itself remained untouched and illegal until the Second Opium War (1856–1860), when a tariff was set on each chest of imported opium. The amount of opium imported into China soared until the late 1870s and early 1880s, when competition from Chinese poppy farmers began to make serious inroads on the market for the Indian-grown drug.

Although many Chinese were involved in the cultivation, preparation, distribution, sale, and consumption of opium, popular sentiment was mixed. The Taiping Rebellion (1850–1864) prohibited opium smoking among its followers, and a number of popular heterodox sects (contrary to or different from an acknowledged standard of belief) and fraternal organizations were dedicated to fighting opium and other intoxicants and vices. Ironically, the Qing government’s battle against the Taipings proved so expensive that the government initiated the lijin (internal transit tax) on all goods traveling through the country to raise revenue, and opium was among the most frequently taxed commodities. By 1890 the Qing state bowed to the inevitable and quietly legalized the cultivation of poppies in China, and although the Qing attempted to use taxation to control the trade, by the early twentieth century opium had become a crucial cash crop, a cornerstone of foreign trade, and a mainstay of China’s medical scene and social life.

As the ailing Qing dynasty clung to power, China’s Manchu rulers launched what was termed the New Policies (xin zheng), a set of reforms designed to modernize the Chinese economy, military, and political system and eliminate what they felt were backward or harmful social customs, such as footbinding and opium smoking. The state used nationalism as the motivation for reform, but opium was so intimately associated with Chinese society that when the Guangxu emperor (reigned 1875–1908) issued an edict launching a ten-year, nationwide anti-opium campaign in September 1906, it met with considerable skepticism inside and outside China.

In fact, the campaign garnered considerable success; it was well conceived and modern in its implementation, although it tended to be more successful in urban areas than in the rural villages and hinterland, where most of China’s poppies were harvested. Bolstered by a treaty signed in 1908 with the British government, in which the latter pledged to reduce the amount of opium exported

A photo from 1874 shows a man addicted to opiates smoking his pipe in a restaurant.
from India into China by one-tenth over a ten-year period, the effort targeted both the supply of and demand for opium. Opium dens were shut down, opium smokers were registered and given photographic licenses to purchase diminishing rations of the drug from licensed shops, treatment centers were opened, and officials attempted to prohibit the cultivation of poppies. The task was daunting, and because the central state could offer little or no funding for suppression in the provinces, much of the campaign was funded by fines on violators of the new restrictions. Chinese officials and reformers were often encouraged and sometimes assisted by foreign missionaries who viewed opium smoking as immoral and socially devastating, not to mention an obstacle to conversion. Ironically, the missionaries who were so critical of the Chinese tended to come from countries that not only profited from the opium trade with China but also widely consumed opium and accepted it as a medical panacea.

The numerous groups with vested interests in continuing the opium trade did not give up easily. However, the campaign had achieved enough success by 1911 that when the agreement with the British was renegotiated in May of that year, China was given the opportunity to end British imports in less than ten years if it could prove that Chinese poppy cultivation had ceased. Smoking continued secretly in many locales, but poppy farmers were the most likely to resist violently and in large numbers. The new republican state continued the anti-opium campaign, but with a new focus on eliminating cultivation, often by force. And as the government cracked down on opium, other opiates, such as morphine and heroin, became increasingly popular.

**Trafficking Rebounds**

As the country fragmented into warlord regimes after the death of republican President Yuan Shikai in 1916, the absence of a strong central government and the growing warlord demand for resources meant a resurgence of trafficking in opium and other drugs. International outcry and the work of Chinese drug reformers, such as the International Anti-Opium Association and the National Anti-Opium Association, had little effect on the situation until Chiang Kai-shek (1887–1975) established his Nationalist republic at Nanjing in 1927. In 1935, after other informal efforts, Chiang announced the launching of the Six-Year Plan to Eliminate Opium and Drugs, a plan with the express intent of bringing the drug trade under government control to eventually eliminate it. Historians continue to debate Chiang’s motivations, but the state did manage to gain considerable control over revenue that otherwise would have fallen into the hands of rival warlords.
although one of Chiang’s more questionable actions involved Du Yuesheng (1887–1951), notorious leader of the infamous Shanghai Green Gang and longtime opium trafficker, in the campaign. As China became engulfed in war, Chiang’s government fled to Chongqing, and the drug trade continued to generate much-needed revenue for the Japanese and the Chinese.

Not long after the founding of the People’s Republic of China (PRC) in 1949, the Chinese Communist Party (CCP) launched another nationwide antinarcotics campaign from 1950 to 1952. The new Chinese state sought to eliminate all vestiges of what it saw as the old, backward, and debauched regimes that had come before. A new China required strong, healthy citizens, citizens who were not caught up in frivolous, destructive old vices such as prostitution, gambling, and opium smoking. The comprehensive goals of the CCP initiative in many ways mirrored those of the effort launched in the late Qing, and the Chinese government initiated a mass campaign intended to eliminate opium consumption, cultivation, and distribution, while providing treatment for habitual users. The first stage relied on public trials and mass arrests, but the tumultuous first years of the new state precluded a concentrated, consistent focus on the antidrug campaign. Beginning in late 1952 the second phase was better organized and relied on mass mobilization and intensive propaganda as well as harsher punishments for violators. Hundreds were executed as the battle against opium was incorporated into broader campaigns against corruption. The campaigns were part of a comprehensive effort on the part of the new state to penetrate and control local society, and they succeeded in eliminating much of China’s illicit drug use.

Since that early campaign the Chinese government has initiated several antidrug campaigns, most of which have resulted in widespread imprisonment and some high-profile executions. Most have focused on traditionally remote and hard-to-govern minority populations, especially in Yunnan Province, part of the infamous Golden Triangle region that borders Myanmar (Burma) and Laos. Post-Mao regimes have relied less on the mass participation that was the hallmark of Maoist campaigns and have had to deal with several developments that promote increased drug use—more expendable cash, a growing income disparity, and the emergence of an enormous “floating” population of migrants whose members flock to the cities and often exist beyond government control.

No Leniency

Twenty-first-century China faces drug problems similar to those confronted by other modern and modernizing societies, and the Chinese government takes an aggressive stance. Drug addicts are required to register with the government, and although close to 1 million had done so at the outset of the twenty-first century, far more have undoubtedly hesitated for fear of punishment. In the past addicts were indeed considered criminals and punished accordingly, but the current official approach to addiction is that it requires treatment. However, many rehabilitation centers use a “detoxification through labor” regimen, and there is no leniency for drug trafficking. Tens of thousands of people involved in the production or trafficking of drugs have been arrested, and hundreds have been executed, but the problem continues to grow. So-called designer drugs such as Ecstasy have become popular, and Chinese authorities are concerned about the spread of methamphetamine production and consumption. Ironically, however, most of China’s registered addicts are hooked on heroin, derived from the opium poppy. Heroin trafficking remains especially difficult to control in Yunnan Province, and as poppy production soars in Afghanistan, that border has also become a problem. To the ultimate chagrin of Chinese authorities, as the economy flourishes and many rural Chinese want a piece of urban prosperity, poppy farming has reemerged in remote areas of China.

Anti-Spiritual Pollution Campaign

Fǎnjìngshén Wūrán Yùndòng
反精神污染运动

The Anti-Spiritual Pollution Campaign, waged against corrupt and bourgeois ideological influences in Chinese society, took place in the autumn of 1983. Within the Chinese Communist Party (CCP), which had largely marginalized the factions of its late leader, Mao Zedong, this campaign was part of a struggle between reformers and conservatives, the latter being critical of some aspects of post-Mao policies of the CCP.

The origins of the Anti-Spiritual Pollution Campaign, which began formally in October 1983 as a movement targeting corrupt and bourgeois ideological influences in Chinese society, date to 1978, two years after Mao’s death, when the party began to reject the key Maoist concepts of class struggle and continuous revolution. Instead, the party advocated the “Four Modernizations,” namely, agriculture, industry, science/technology, and national defense (but not what dissidents called the “Fifth Modernization,” that is, democratization). It also advocated the policy of “reform and opening,” that is, reforming the economic system and opening China to trade with other countries, especially those in the West.

In late 1979 and 1980 forces associated with CCP leader Deng Xiaoping and his policies of reform began calling for the establishment of a “socialist spiritual civilization,” a set of ethical principles to be followed by all members of society, ignoring any notion of class. These reforms provoked a reaction within the CCP. An emerging conservative faction became increasingly concerned about the implications of these reforms for Chinese socialism. As part of a wider strategy to combat the excess and errors of these reforms, conservatives tried to limit the spread of “bourgeois liberalization.” The Anti-Spiritual Pollution Campaign of 1983 was one aspect of this effort.

In 1980 conservatives publicly called on the party to combat “bourgeois liberalization.” In the autumn of 1983 calls to combat “spiritual pollution” per se began, although the campaign did not formally begin until the Second Plenum of the Twelfth Central Committee adopted the “Decision of the Central Committee of the Communist Party of China on Party Consolidation” on 11 October 1983. The decision called for the initiation of a three-year movement to consolidate the party, including forging greater ideological unity, rectifying work style, purifying party organizations, which meant removing those members who had risen to prominence during the Cultural Revolution (1966–1976), and fighting “spiritual pollution” while being clear that this campaign would not be a mass campaign like the Cultural Revolution in which the masses had been called on to evaluate and rectify the errors of party members.
Ideological Influences

The party’s campaign against “spiritual pollution” generally targeted corrupt and bourgeois ideological influences undermining the “Four Cardinal Principles,” socialist and communist causes, and the leadership of the party. More specifically, it targeted pornography, some forms of advertising, and—among intellectual and literary circles—such notions as humanism, alienation, and modernism.

Humanism and alienation are categories from the early writings of the German socialist Karl Marx that Maoists and other Marxists frequently dismissed as the immature writings of the “early Marx.” Humanism implies a universal human nature rather than one determined by material conditions and class struggle. Alienation suggests disaffection from this universal human nature and implies a critique of socialism by implying that even under socialism incorrect political and economic practices still cause alienation. Modernism, as a school of literature, was criticized for its implicit critique of not merely the Cultural Revolution but also virtually the entire history of the Chinese revolution.

Like the Cultural Revolution, which had failed to provide a clear definition of class, the campaign against spiritual pollution never had a clearly defined, comprehensive, or concrete target. This ambiguity allowed critics of the unfettered reforms to attempt to expand the scope of the campaign. The critics were mainly some allies of Deng Xiaoping, such as Deng Liqun, Chen Yun, and Hu Qiaomu. Although they had all suffered during the Cultural Revolution, they were still concerned about loosening the party’s control over intellectuals and culture and the spread of “ultra-individualism.” Critics of the party’s “reform” policies also included limited numbers of “leftist” party members. Because of the lack of a clear definition of “spiritual pollution,” critics rapidly attempted to extend the range of criticism to peasant entrepreneurs, who were seen as excessively focused on money, as well as forms of Western “decadence,” such as Western dress styles and permed hair.

A series of billboards along a street advertise everything from beauty cream to medicinal products. During the Anti-Spiritual Pollution Campaign the Chinese government attempted to combat Western materialist influences without upsetting China’s economic growth. PHOTO BY JOAN LEBOLD COHEN
Within two months of the campaign’s inception, because of fear that it would negatively affect foreign investment and trade, a key element of the “reform and opening” policy, Deng Xiaoping, who had initially supported the campaign, made it clear that it was to be reined in. By the end of 1983 it had ceased to exist in any meaningful fashion. Nonetheless, the campaign resulted in several of the more liberal opponents of the campaign in the higher levels of the party losing their positions.

Through the mid-1980s and after the 1989 “democracy movement” and Tiananmen protests, as well as the 1991 collapse of the Soviet Union, party conservatives who had supported the 1983 campaign against “spiritual pollution” continued to fight against “bourgeois liberalization” (such as discussions or advocacy of Western forms of democracy) and the policy of “peaceful evolution” (which, they believed, the West could use to undermine socialism in China). They even went so far as to characterize the reform road as a de facto road to capitalism.

Turning the Tide

However, in 1992 Deng Xiaoping undertook his six-week “Southern Tour” to the “special economic zones,” the controversial areas of experimentation showcasing the reform and opening policy, including significant foreign investment and new market-based forms of economic organization and development. The rapid economic development revealed by this trip turned the tide within the party decisively in favor of Deng’s overall policies of economic—but not political—reform, that is, economic reform without democratization.

China today is dominated by various groups of reformers whose policies have led to virtually unprecedented economic growth. However, with that growth has come increasing economic inequality, rising corruption, and many of the very practices criticized in the campaign against spiritual pollution and other subsequent campaigns.

Anyang was the center of Chinese culture and power during the Shang dynasty (1766–1045 BCE). Archaeological excavations have unearthed many artifacts that showcase the importance and predominance of its civilization, most notably the famous Bronze Age “oracle bones.” Anyang’s Yin Xu excavation site became a UNESCO World Heritage Site in 2006.

Anyang, a prefecture-level city in today’s Henan Province, was the last royal center of the Shang dynasty from 1300 BCE to 1046 BCE. The Shang (1766–1045 BCE) were also named the Yin; therefore, Anyang is also called Yin Xu (Yin Ruins). Around 1300 BCE, King Pangeng moved his capital here, and the city reached the height of its development during King Wuding’s period (1250–1192 BCE). Eleven kings were buried in Anyang; all the kings’ tombs, along with the tombs of some members of the royal family, were at Houjiazhuang, north of the Huan River. Some lower-ranking elite were buried near Xiaotun village on the south of the river. A temple-and-palace complex, which formed the core city of Anyang, was built at Xiaotun, surrounded by an artificial trench and the river. Workshops for pottery, casting bronzes, bone working, and carving jade, as well as cemeteries, were spread out in a huge area. Beginning with the discovery of oracle bone inscriptions in 1899, fifteen excavations were undertaken from 1928 to 1937, and ongoing excavations have continued since 1950, but it is still too early to deduce the original city plan of the Shang capital.

The locations of the temples, palaces, and cemeteries for royalty and commoners, as well as human sacrificial pits, were based on a hierarchy and suggest social position. The orientation certainly was related to a religious, cultural, and social belief systems, and the Shang elite scrupulously adhered to these beliefs. The burial sites and the associated burial rituals tell us that the Shang people were possibly divided into clans. The layout of Anyang was configured in three distinct sections: the core city, the inner city, and the outer city. The social class and position of people buried in a royal cemetery can be determined by considering its distance from the core city: the farther the location from the core city, the lower the rank of its interred occupants. Moreover, even when the population increased and the city expanded, this layout did not change, showing that the belief in hierarchy remained very strong. The scale and sophistication of the hierarchical system in Anyang did not exist simultaneously in any other urban center in East Asia.

The advanced designs of the ritual bronzes cast in Anyang represent the quality of technology at the time and some of the greatest achievements of the Bronze Age civilization in Asia. Thirty types of bronze vessels of various sizes that were used for ritual offerings of food and liquor have been unearthed there. The excavated jade carvings discovered in Anyang are a part of the unique jade culture of China, and carved bones like the ones uncovered in Anyang have never been found anywhere else.
Anyang was the center of China at the peak of the Shang dynasty. Peoples or nations from as far away as the South China Sea paid tribute to the Shang, and many people who went to war with the Shang were captured and brought to Anyang to be sacrificed to the gods or to serve as slaves. By the very late Anyang period, the Zhou people grew stronger in the west, in today’s Shaanxi Province; they conquered the Shang in 1046 BCE.

Seafood is already a staple in the Chinese diet, but domestic consumption is projected to rise 40 percent by 2020. Of China’s total seafood output, 64 percent comes from aquaculture (the farming of aquatic life), making it the only country in the world where the amount of cultivated seafood is greater than the wild catch.

Aquaculture—the farming of any aquatic life, including freshwater and saltwater fish, mollusks, shellfish, crustaceans, and plants—is a vibrant industry in China. Several varieties of carp compose most of the cultivated freshwater species; shellfish dominate the saltwater market. However, as China’s population becomes wealthier, demand is growing for higher-value species—notably grouper—which require high inputs of “trash fish,” thereby putting an increasing strain on wild stocks around the world. Aquatic plants, such as kelp, account for 27 percent of total aquaculture output. Since 1978, China’s aquaculture production has increased 490 percent, making it now the largest in the world, and accounting for 57 percent of the global output.

Aquaculture is China’s largest “farmed” export, with Japan, the United States, and South Korea as the main destinations. Local governments promote aquaculture as a poverty-alleviating industry and have therefore subsidized production of lucrative species such as tilapia. China supplies 70 percent of the tilapia imported into the United States and is also its fourth largest supplier of shrimp (shrimp and tilapia are the first and fifth most popular seafood, respectively, of U.S. consumers).

Aquaculture is practiced all over China and aquacultivated areas are increasing, with carp farms being the most widespread. However, other fish are restricted to regions for climate and environmental reasons. For example in 2006, Guangdong, Guanxi, and Hainan produced 81 percent of the nation’s tilapia; Hubei, Sichuan, and Jiangsu produced 56 percent of the nation’s catfish; Shandong, Fujian, Guangdong, and Liaoning provinces accounted for 80 percent of the total shellfish production; shrimp and prawns are produced mainly in Guangdong as well as Jiangsu, Guangxi, Zhejiang, and Hainan; and eel is produced mainly in Fujian, Guangdong, and Jiangxi.

Because China’s waterways are highly polluted, food safety has become a major concern for Chinese aquaculture. Besides municipal and industrial wastewater contamination, mercury emissions from China’s coal-fired power plants are another potential source of aquaculture contamination. Statistics on mercury in Chinese fish are scarce, but Chinese coal is believed to be responsible for much of the mercury contamination in fish in the western United States.

International concern about food safety has cost China’s aquaculture dearly, as countries ban species they have discovered to be contaminated. Two major cases include the 2005 eel bans in Japan and the 2003 shrimp bans in the European Union—both devastated these important aquaculture sectors in China. Chinese consumers also are
increasingly concerned about water pollution, dangerous farming practices, and poor processing in the aquaculture industry that pose serious threats to human health. The rapid development of China’s aquaculture industry is also a major polluter of rivers, lakes, and coastal waters. Moreover, this industry’s huge demand for fishmeal is driving stock depletion in the oceans.

**Environmental Impacts**

Raising carnivorous species, such as salmon and shrimp, tends to produce some of the most detrimental environmental impacts because of the amount of antibiotics and waste they produce. However, hardier herbivorous fish that require fewer chemical and organic inputs can also create environmental problems when they are farmed too intensively. In China, the high-density farming of herbivorous fish increasingly faces the same challenges of disease, overmedication, and nutrient runoff as the country’s concentrated land-animal feeding operations. Some environmental impacts causing concern domestically and internationally include:

**Oxygen Depletion and Algae Blooms**

Runoff of uneaten food and effluent from fish farms is a growing problem in China. In the past, freshwater fish fed off naturally occurring organic material in ponds. However, the intensification of farming and the increased use of manufactured feed has led to more uneaten food, effluent, and pollutants in the waterways; this can cause eutrophication, the uncontrolled growth—and decomposition—of algae and other organisms that deplete the oxygen supply in the water, choking other life forms. For example, shrimp consume only 20 percent of their food on average; the rest washes out to sea or settles into the soil, fouling the ponds.

**Antibiotics, Pesticides, and Fungicides**

Many fish farmers are individuals, rather than companies, and they often over-apply or misuse antibiotics, pesticides, and fungicides to clear the water of other creatures, reduce parasites, control disease, and boost weight gain of seafood grown in severely overcrowded conditions. Antibiotics, either applied directly to the water or that have passed through the fishes’ digestive systems, are not biodegradable and persist in the surrounding environment, threatening wild fish stocks.

**Habitat Destruction**

Lucrative fish markets prompted many Chinese rice producers in the early 1990s to switch into intensive aquaculture production. This trend, in conjunction with rapid urbanization, raised concerns about grain security and led the Chinese government in 1994 to establish the Basic Farmland Protection Regulation, which enforced a zero net-loss of grain or oilseed farmland. Nevertheless, China’s aquaculture output continues to rise as more natural bodies of freshwater and more marine coastline are converted into fish farms. Diseases and pollution from overcrowded fish farms, particularly shrimp pools, are often pumped out into natural waterways, endangering native species.

**Monoculture and Invasive Species**

A major challenge for aquaculture is the need for fast-growing species that can withstand the conditions of farms, namely overcrowding and high levels of nutrients and ammonia. Monoculture of these fast-growing fish can lead to a reduction in genetic diversity and makes farms susceptible to diseases. The quest for fast-growing species also brings in foreign species that can become invasive. Amazonian snails, for example, were imported for food and are responsible for decimating 1,600 square kilometers of farmland in China, and countless acres of natural habitat. The other disadvantage of this type of farming is the possibility of an epidemic disease that destroys the stock. Before 1993, China was the world’s top shrimp producer until an epidemic of white spot decimated the shrimp population. The market has never fully recovered.

**Food Safety Concerns**

The Ministry of Health (Luan 2007) reported in March 2007 that 196 people died of food poisoning in China the
previous year. Unsafe and undercooked aquacultural products are an integral component of this total figure. A major challenge to food safety in China is the structure of the aquaculture industry. First, there are many widely scattered players involved in the production of the feed, the farming and the processing. It is thus highly challenging, and expensive, to standardize and monitor the veterinary care and processing of the fish. Second, there is a strong preference for live and undercooked fish in China, increasing the risks to consumers and highlighting the need for timely monitoring and testing.

While the Ministry of Health issues the regulations, food safety rests essentially in the hands of local government enforcers, which in the case of aquaculture often lack the motivation or capacity to monitor strictly. According to the Chinese scientist Lei Jilin in an interview with Xinhua News Agency, the local government agencies entrusted with monitoring fish-related food safety are either doing their jobs poorly or not at all. The Shanghai food-quality inspections appear to be the most successful, as they are often the first to discover large safety mishaps. Further complicating the food-safety issue and eroding consumer trust is the fact that, while investigations are publicly announced, the findings of the investigations of farms and market studies are often not publicized.

One final concern regarding herbivorous fish is the farming practice of using human and animal waste as feed. This practice has proved particularly suspicious with regards to avian influenza around Qinghai Lake where thousands of migratory birds fell ill in 2005 near several large carp farms and feed-manufacturing facilities. There is some speculation that poultry-litter-based fish feed may have played a role in spreading this disease to wild bird populations.
HIGH-PROFILE AQUACULTURE-RELATED FOOD SCARES FROM 2006 TO 2007

- 14 October 2008: Fish in Lake Tai found to contain an excessive amount of formaldehyde.
- 19 February 2008: China recalls pesticide-tainted mackerel from Japan two weeks after tainted dumpling scandal. Although these are believed to be added at the manufacturing stage, they still impact China’s seafood trade.
- 30 April 2007: The New York Times (Barboza & Barrionuevo) reported that melamine scrap, believed to have sickened 14,000 U.S. pets, is commonly used in fish feed in China. Melamine is added to animal feed as a synthetic nitrogen enhancer, making the feed appear to have more protein and increasing its value.
- 26 April 2007: Wal-Mart removed Chinese catfish from U.S. stores due to antibiotic contamination. It was the state of Alabama, not the U.S. Food and Drug Administration, that discovered the contamination.
- November 2006: Eleven out of fifteen samples of Mandarin fish from China tested positive for malachite green in Hong Kong.
- 22 November 2006: Carcinogens (chloramphenicol, malachite green, and furazolidone) were found in turbot in Shanghai. Turbot sales were subsequently suspended in Shanghai, Beijing, Shenzhen, and Taoyuan. Turbot is a species of flatfish with low disease resistance that requires considerable and careful veterinary input. One hundred percent of the Shanghai sample tested positive.

A fisherman carrying his “butterfly nets” in Zhejiang Province, 1979.
PHOTO BY JOAN LEBOLD COHEN.
October 2006: Taiwan banned imports of hairy or mitten crabs from China due to traces of carcinogens.

August 2006: 87 people were diagnosed with meningitis after eating raw or undercooked Amazonian snails in Beijing.

Some Positive Steps

With wild catch rapidly decreasing due to over-fishing and pollution in China’s freshwater and coastal areas, China must increasingly turn to aquaculture to supply its protein base. The trouble with aquaculture is essentially twofold: It uses rudimentary and even dangerous farming practices, and it has weak or nonexistent food-safety monitoring. The effect is environmental degradation and compromised human safety in both domestic and foreign markets.

DEVELOPMENT OF SAFER FEEDS AND FARMING METHODS

With aquaculture and demand for fish rising substantially in China, fish farming is intensifying. Feed is a major source of concern and an integral part of intensification. The Chinese government’s priority for food security has led it to commit considerable resources to agricultural and fish research that has produced some promising new options for feeds, fish species, and farming practices. Such research holds the promise of promoting ecologically safer fish-farming practices that also will help protect human health and limit China’s use of wild ocean fish as fishmeal. Some new feeds being developed include:

- Yeast-based feed. According to World Resources Institute, “Chinese researchers are developing a protein supplement based on yeast that can substitute for more than half the fishmeal in aquaculture feed preparations.”
- Soy-based feed. As of 2007, China’s aquaculture industry used 4.5 to 5 million metric tons of soy meal a year (Ellis & Turner 2007). Some species, such as tilapia, one of China’s staple fish, can tolerate 80 percent soy in their diets. Other high-value fish can tolerate only 10 percent soy; however, even a small reduction in ocean fishmeal dependence will relieve some stress on global oceans.

Another area of research is identifying fish species with higher survival rates and faster growth rates that may reduce the need for chemicals to sustain profitable production.

Integrated polyculture systems, once the norm in China, are a more sustainable solution. One living example is the rice-field carp of Qingtian in Zhejiang Province. In Qingtian, terraced rice patties were stocked with carp by naturally flowing river water. However, farmers have intensified carp production with the addition of manufactured fish feed and by erecting concrete barriers to deepen their ponds. The damming of such rivers to create carp pools has led to increasing problems of eutrophication, interrupted water supply to farms and communities, and diseased fish. In order to encourage a return to a more environmentally friendly integrated polyculture system, the government could develop a new certification for organic rice-patty carp, which could help the Qingtian farmers create lucrative markets in the nearby tourist centers of Hangzhou and Suzhou.

FOOD MONITORING A NEW PRIORITY

As is true in the case of other environmental and health challenges in China, many superb laws exist, but monitoring and enforcement tend to be weak. During the 2006 turbot scare, it merits mention that the three farms highlighted by name as responsible in the Chinese news media were subsequently fined and ordered to suspend sale for violating bans on antibiotics in fish. The 2008 Olympic Games played a positive role in accelerating food safety progress in the Beijing area primarily by creating a “safe list” of food suppliers, which notably has been done in Hong Kong with aquacultural products from Guangdong, but there is still much to be done to address the systemic regulatory failures in the vast aquaculture system that most dramatically affect those outside big cities. Some positive trends include:

- March 2007: The Ministry of Health released a draft of a new food safety coordination law to the public via the Internet.
A fisherman at Guilin is aided by cormorants, trained since ancient times in China to catch and bring back fish to their owners. PHOTO BY PAUL AND BERNICE NOLL.

- March 2007: The Fresno Bee reported that Global Food Technologies signed an agreement with the China Seafood Certification Institute to develop a branded food safety program for seafood beginning with one billion pounds of seafood by the end of 2009.
- November 2006: The Fisheries Bureau of the Ministry of Agriculture announced a nationwide inspection targeting forbidden chemicals in the fish market.

As China develops, seafood will no doubt continue to play a major role in nutritional security as well as food safety. However, with the population becoming more wealthy, red meats and high-value fish species, such as grouper, salmon, and black seabass will take greater market shares at an ever higher threat to the environment. Increasing domestic demand for processed, rather than live, seafood will present new food safety challenges to the developing food-safety system. In the last two years, international and domestic pressures have led the central government to shift its focus to food safety, particularly in seafood. Given the chronic shortages of land and water in China and continuing population growth, regulators and policy makers must continue to prioritize the food production and distribution systems to conserve resources and protect human health. There is great opportunity to increase production through more scientific farming practices.

In terms of exports, China’s aquaculture is being more scrutinized. After the food bans in 2007 from major importers, China will no doubt diversify its sales. The United States has taken a proactive approach to continuing trade in aquaculture by signing an agreement between the Department of Health and Human Services and the General Administration of Quality Supervision, Inspection and Quarantine to cooperate and streamline the inspection process for Chinese aquaculture. In 2008,
the U.S. Food and Drug Administration also opened offices on the ground in China, which will play a role in this process.

Modern field paleontology and archaeology were introduced to China in the early twentieth century. Fossil remains have provided new insights into the evolution of life, paleoanthropological remains on the evolution of mankind, and archaeological excavations on the development of human cultures. The last twenty years have seen a marked improvement in research quality, an explosion of new data, and several scientific breakthroughs.

Archaeology (the study of material remains of past human life), and paleontology (the study of life of the geological past and the evolution of life) in China share a common past. The first generation of Western-educated Chinese scholars worked together in the field as geologists, paleontologists, and archaeologists surveying the country’s natural resources. Paleontology was used to find possible locations of natural resources, and to define the age of geological strata. Methodology from paleontology and geology was used in archaeology studies when archaeological remains were found and excavated during the survey work.

The first reference to fossils in China is found in the Shan Hai Jing (山海经, Classic of Mountains and Seas), mainly compiled between the fourth and first centuries BCE. It contains stories of mythical creatures of the past. The Qian Han Shu (前汉书, History of the Former Han Dynasty, c. 100 CE) mentions the find of dragon bones (龙骨, fossils) in 133 BCE during work on a canal. Several sources during the next millennium refer to fossils as ancient animals and plants, and some books have passages remarkably similar to those in modern paleontology. The Yun Lin Shi Pu (云林石谱, Stone Catalogue of Cloudy Forest, 1033 CE), for instance, contains detailed descriptions of fossil fishes. Fossils have been collected since ancient times and used in traditional Chinese medicine for their supposed magical powers and ability to cure disease. Still, in the 1950s, paleontologists made major discoveries by asking the local population where they collected their dragon bones.

The earliest Chinese experiments in what resembles modern archaeology were made during the Song dynasty (960–1279) when ancient inscriptions found on stones and bronzes were studied and catalogued. This tradition, although interrupted at the beginning of the Yuan dynasty (1279–1368), continued well into the late Qing dynasty (1644–1912).

Republican China (1912–1949)

The first modern survey that included some Chinese paleontology was made in the latter part of the nineteenth century during expeditions to China by the German Ferdinand von Richthofen (里希霍芬, 1833–1905). However, not until the turn of the next century was the potential of Chinese fossils realized when Western visitors found dragon bones in medicine shops. The discovery began
a fossil hunt in the drug stores. In 1914 the Swedish geologist Johan Gunnar Andersson (安特生, 1874–1960) was hired by the Chinese government to conduct mineralogical surveys around the country. He became interested in the paleontological and archaeological remains that he came across during his work. In the mid-1910s he met the Chinese scholar Ding Wenjiang (丁文江, 1887–1936), the first head of the Geological Survey of China. Trained in Japan and Britain with majors in geology and zoology, Ding represented the first generation of Chinese scholars with an education in modern science. With his background in zoology, he was also interested in paleontology. The two men began to cooperate in a search for fossils, and Ding, in a program to train geology students in fieldwork, sent students to Andersson. From 1920 onward the education of a coming generation of Chinese paleontologists was furthered with the arrival of the U.S. geologist and paleontologist Amadeus W. Grabau (葛利普, 1870–1946), who was invited by Ding.

In 1921 Andersson initiated excavations at the site Zhoukoudian 周口店, 50 kilometers from Beijing, where the tooth of a 500,000-year-old hominid (any of a family of erect bipedal primate mammals comprising recent humans together with extinct ancestral and related forms) was found the same year by the appointed excavator, the Austrian-Swedish paleontologist Otto Zdansky (鄂登斯基, 1894–1988). The tooth belonged to a new species, popularly called “Peking Man” 北京
人，which was announced in 1926 and later named *Homo erectus pekinensis*. The find stirred attention around the world and had a profound importance for research on early human development. Continued investigations at Zhoukoudian were made by a Sino-Western institute—the Cenozoic Research Laboratory—the precursor of the present Institute of Vertebrate Paleontology and Paleoanthropology (IVPP). The lab was placed under the Geological Survey of China, and its first head was Davidson Black, a Canadian physician of the Peking Union Medical College. Several Chinese students who later influenced the development of paleontology in the country, such as Yang Zhongjian (杨钟健, 1897–1979), Pei Wenzhong (裴文中, 1904–1982), and Jia Lanpo (贾兰坡, 1908–2001), started their careers at the laboratory. Many of them were students of Grabau. Chinese specialists such as these also took part in surveys of the Huang (Yellow) River area at this time and in the search for paleontological and archaeological remains during the interdisciplinary Sino-Swedish expedition to northwestern China in 1927–1935. Grabau himself made surveys of great importance. In the 1920s, for instance, he was the first to describe the Jehol biota (热河生物群, the flora and fauna of a region) in northeastern China, which during the century came to reveal a whole ecosystem of fossils dating to 125 million years. Other influential foreign paleontologists of the time included Father Pierre Teilhard de Chardin (德日进, 1881–1955) of France, who surveyed sites in Ningxia Autonomous Region, Shaanxi Province, and Inner Mongolia during.

Yangshao 1921. A rare photo from the period when Chinese experts first participated in excavations in China. Left to right: the archaeologist and geologist Yuan Fuli of Tsinghua University (trained at Columbia University); Johan Gunnar Andersson, the Swedish geologist turned archaeologist who led the excavations; the village chief, Mr. Wang, and a local preacher also named Mr. Wang. The investigations revealed the Yangshao culture (仰韶, c. 4500–2500 BCE). This major discovery of the Neolithic era laid the foundation of prehistoric archaeology in China. From J. G. Andersson. (1934), *Children of the Yellow Earth*. USED WITH PERMISSION OF THE MUSEUM OF FAR EASTERN ANTIQUITIES, STOCKHOLM.

the 1920s and assisted in the Zhokoudian research, and Roy Chapman Andrews (罗伊查普曼安德鲁斯, 1884–1960) of the United States, who in several expeditions during the 1920s searched for paleontological finds. The latter worked mostly outside the country, but he also did extensive surveys in Inner Mongolia, where he discovered fossils of dinosaurs and mammals.

**ARCHAEOLOGY (1912–1949)**

Modern field archaeology was introduced in China around the turn of the twentieth century when a number of foreign scholars—explorers, archaeologists, and paleontologists—went to Chinese Central Asia, mainly in search of remains along the ancient Silk Roads. The Swedish geographer Sven Hedin (斯文·赫定, 1865–1952) surveyed ruins in Xinjiang Uygur Autonomous Region and discovered the site of Loulan 楼兰 in the Tarim Basin in 1900. Sir Aurel Stein (斯坦因, 1862–1943), a British-Hungarian archaeologist, conducted excavations on sites such as Khotan 和田, Niya 尼雅, Bezeklik 伯孜克里克, and Loulan. He also visited Dunhuang 敦煌 in Gansu Province, where a Daoist priest had found a huge amount of ancient documents in the Buddhist Mogao caves 莫高窟 in 1900. Many of these were purchased by Stein and later by the French sinologist Paul Pelliot (伯希和, 1878–1945). The Germans Albert Grünwedel 格伦威德尔 and Albert von Le Coq 勒科克 made extensive investigations in Xinjiang, as did Russian explorers, who already had reported on historical remains in the area in the late nineteenth century. Japanese scholars, such as Otani Ko−zui (小泉光, 1876–1948) and Torii Ryozo (鳥居龍藏, 1870–1953), also organized expeditions. The latter found Neolithic (8000–5500 BCE) remains such as spearheads and polished stone axes during his investigations in the Liaodong peninsula in 1895 and discovered the prehistoric site of Hongshan (红山, c. 3800–2700 BCE) in Inner Mongolia in 1908.

China’s participation in these surveys increased after the May Fourth Movement (1917–1921), when many Chinese students who had gone abroad to acquire knowledge of Western sciences returned and began collaborative projects with Western scholars. In the early 1920s Andersson had become more interested in studies of the archaeological remains he found during his surveys around the country. He hired young Chinese scholars, such as Yuan Fuli (袁复礼, 1893–1987), a former student at Columbia University, and Li Ji (李济, 李济, 1896–1979) from Harvard. Andersson included Chinese specialists in archaeological excavations for the first time when he found painted pottery near the village of Yangshao in Henan Province in April 1921. The Yangshao culture (仰韶, c. 4500–2500 BCE) soon proved to be one of the major discoveries on the Neolithic era. From the pottery’s similarity to painted pottery found in Central Asia and the Near East, Andersson argued that Chinese culture might have originated from the west. To back his theory he went...
to northwestern China, where he found a western outpost of the Yangshao culture, the Majiayao culture (馬家窯, c. 3500–1500 BCE), and the early Bronze Age culture of Qijia (齊家, 2400–1900 BCE). The western-origin hypothesis was later abandoned, and some of the pottery is now believed to have spread westward from central China to its borders.

**ORACLE BONES**

The first truly independent archaeological excavations that took place at this time symbolically restored China’s self-image. Oracle bones had been found around 1900 in Anyang 安阳, northern Henan Province, and the early investigations of the ancient bone inscriptions caused Luo Zhenyu (羅振玉, 1866–1940) to claim that the site might be the location of the late Shang dynasty (1766–1045 BCE) capital Yinxu 殷墟, mentioned in the Shiji 史記, Records of the Grand Historian), written about 100 BCE by Sima Qian (司馬遷, c. 145–90 BCE). This evidence was not enough, however, to prove the existence of the Shang dynasty, which many believed to be a myth. In 1928 the Chinese Nationalist Party (Guomindang) government made field investigation at Anyang a the priority when it formed an archaeology department within the Institute of History and Philology in the Academia Sinica. Evidence of a highly advanced Bronze Age culture as well as architectural remains of palaces and temples were

**The excavation site at Zhoukoudian in 1921, with Otto Zdansky to the far left. The same year he made the first discovery of Peking Man—a single tooth. In the center below is Walter Granger (葛兰格, 1872–1941) from the American Museum of Natural History in New York, who visited Zhoukoudian to introduce modern excavation techniques. From J. G. Andersson. (1934), Children of the Yellow Earth. Used with permission of the Museum of Far Eastern Antiquities, Stockholm.**
unearthed during ten seasons of work led by Li Ji. In 1936 the former capital’s archive was found, finally proving the existence of the Shang dynasty. More discoveries by the archaeology department followed, such as the Neolithic Longshan culture (龙山, c. 2500–1700 BCE) in Shandong Province. These finds showed that connections existed between the Shang dynasty remains and the Neolithic cultures found so far. Li Ji’s student, Xia Nai (夏鼐, 1910–1985) was later able to put these pieces together to develop a correct chronology and classification that Andersson first proposed for China’s prehistoric cultures.

**Maoist Years (1949–1978)**

The Japanese occupation and the Chinese Civil War ended the early formative years of Chinese archaeology and paleontology. The 1950s brought establishment of two new major organizations for paleontology research that would play leading roles until the late 1970s. These were the Nanjing Institute of Geology and Paleontology (NIGP) and the Institute of Vertebrate Paleontology and Paleoanthropology, both organized under the Chinese Academy of Sciences in Beijing. Some of the remaining Chinese staff of the Cenozoic Research Laboratory came to work under the IVPP, among them Yang Zhongjian, who became its first head. Soon excavation at Zhoukoudian resumed, and large surveys of geological and paleontological resources, supervised by these institutions, were initiated throughout the country. The work was mainly aimed at finding new evidence of Peking Man, whose remains had been lost during the war, and at collecting new paleontological data. A large number of fossils were also discovered and identified during this time, for example, the dinosaur *Tsintaosaurus* found in Shandong Province and described by Yang Zhongjian in 1958. The most important paleoanthropology finds were made in the early 1960s in Lantian, Shaanxi Province, where hominid fossils of *Homo erectus* dating to 1.1 million years were discovered in 1963 and 1964. A year later a 1.7 million-year-old hominid fossil was found in Yuanmou 元谋, Yunnan Province.

With the establishment of the Communist regime in 1949, several scholars who had developed an independent Chinese archaeology took refuge with the Chinese Nationalist Party regime in Taiwan, where their work continued at the Academia Sinica. Mainland China established the Chinese Academy of Science, whose head, Guo Moruo (郭沫若, 1892–1978), founded the Institute of Archaeology. Archaeological work there was largely managed by Xia Nai.

The focus on China’s Neolithic age was resumed, and a number of important discoveries were made in the 1950s and 1960s. Excavations at Dawenkou in Tai’an, Shandong Province, enabled a link to be made between early Neolithic southern and northern China. The painted pottery of the Dawenkou culture (大汶口, c. 4500–2500 BCE) indicated contacts with the Yangshao culture, while other artifacts had a close resemblance to those of the later Longshan culture. Large excavations at the Yangshao site Banpo 半坡, near Xian in Shaanxi Province, revealed an entire village dating to about 4800–3600 BCE.

Research on the formation of early cities and the development of ancient China led to new discoveries. Several Shang dynasty remains older than those at Anyang were found. The most important were at Erligang 二里岗 near Zhengzhou, which was probably the capital between 1500 and 1400 BCE. In the late 1950s scientists found an even older Bronze Age culture, which some scholars believe is proof of the existence of the Xia dynasty (2100–1766 BCE), the predecessor to the Shang dynasty. At Erlitou 二里头 in Yanshi, Henan Province, a fortified city and a palace dated to between 1900 and 1500 BCE were unearthed. Also remains from the Eastern Zhou dynasty (770–221 BCE) were discovered and excavated during this time, as, for instance, in 1956, when the capital of the state of Jin between the years 584 and 450 BCE was found at Houma 侯马 in Shanxi Province.

Understanding of prehistoric China had increased significantly before the Cultural Revolution (1966–1976). Scientific work came to a halt, both in archaeology and paleontology, in 1966, but input from unexpected discoveries and rescue excavations in archaeology continued. The buried terra-cotta army of the Qin emperor (third century BCE), for instance, was found in March 1974 near Xian in Shaanxi Province when local peasants were drilling a well. Beginning in 1972 archaeological exhibitions played an important part in opening up China and attracted huge interest from the outside world. They made the Chinese government aware of the potential that archaeological remains had for the country’s international image. Archaeology became therefore one of the first sciences to resume its work. In 1973 south of Hangzhou Bay,
the Hemudu culture (河姆渡, 5500–4770 BCE) was found. Excavations at the marshy area of this offshore island culture in northern Zhejiang Province demonstrated large finds of unusually well-preserved materials as well as of house remains that were different from those unearthed in northern China. In 1976 Lady Fu Hao's 妇好 tomb was discovered. It contained artifacts of royal life during the Shang dynasty. In Hubei Province the next year soldiers found the tomb of Marquis Yi of Zeng 曾侯乙, who died in 433 BCE. Among the remains recovered from the grave were more than 120 musical instruments—a unique collection in the world.

Paleontology Today

Methodology and technology in Chinese paleontology and archaeology did not progress despite such important discoveries. The two sciences developed largely in isolation from the outside world for four decades, and the need to catch up was urgent. Although a new generation of scholars was eager to get in contact with the research community abroad, the ban on Sino-foreign fieldwork remained. However, in 1986 a collaboration paved the way for others. It was the Sino-Canadian Dinosaur Project, a series of expeditions conducted between 1987 and 1990 to collect Jurassic (c. 200–145 million years ago) and Cretaceous (c. 145–65 million years ago) vertebrates in northern China. With the lifting of the Sino-foreign fieldwork ban in 1991, a wave of collaborations followed: Foreign scholars visited, and Chinese paleontologists went abroad for research studies and exchange. The 1980s and 1990s brought a rapid growth of university institutions, which developed their own research agendas, thus challenging the monopoly of the IVPP and NIGP. The institutional competition, the open door policy, and an increased desire to publish results abroad led to improved research quality and to an explosion of new data and scientific breakthroughs.

In July 1984 the Chengjiang fauna 澄江生物群, said to be one of the most important paleontological finds of the century, was found in Yunnan Province by Hou Xiangguang (侯先光, b. 1949). Apart from the discovery of almost two hundred species so far, this rich fossil deposit gives vital information on the evolution of primitive plants and animals. The oldest fossil vertebrate in the world, for instance, was reported from the site of Ercaicun 耳材村 in 1999. It revealed a jawless early fish, dating from the Lower Cambrian (c. 530 million years ago), thus pushing back the history of vertebrates another 50 million years. Of equal, if not more significance, was the discovery of fossil embryos dating from 570–590 million years ago in the Doushantuo 陡山沱 formation in Guizhou Province in 1998. This discovery gave evidence of the existence of animal life before the so-called Cambrian explosion, a time in evolutionary history when suddenly a large number of animal fossils appeared. The previous lack of Precambrian finds had been a mystery to paleontologists since the time of the British scientist Charles Darwin. The discovery has led to similar and even older finds elsewhere in the world. The Jehol biota in Liaoning Province also was on the agenda again from the late 1980s onward. First the bird Sinornis was found, then Confuciusornis, then a series of discoveries that culminated in the unearthing of feathered dinosaurs such as Sinosaurus and Protarchaeopteryx. These fossils challenged the theory that birds and dinosaurs had developed separately and gave insights into the evolution of flying. Recent Chinese paleoanthropology has also shed light on the development of our own species. The oldest hominin fossils in the country, for instance, were found in 1985 at Longgupo 龙骨坡, Sichuan Province, and investigations have revealed stone tools and dated the fossils to 1.9 million years.

Archaeology Today

The renewed study of the Neolithic era since the late 1970s has focused on the relationship between early farming societies and the spread of agricultural techniques. Radiocarbon dating, introduced to China in the 1960s, is used more frequently. Evidence for rice production was found in the Hemudu culture, which was a site in contact with the Majiabang culture (马家浜, c. 5000–4000 BCE)—a rice-producing economy as well—near Shanghai. The Majiabang culture in its turn showed resemblances to millet-producing cultures in the north, such as the Dawenkou. The oldest millet grains found so far in the Huang River valley were unearthed at the site of Peiligang (裴李岗, 5500–4900 BCE) in Henan Province. The oldest evidence of rice cultivation comes from
Pengtoushan 彭头山, Hunan Province, dating to at least 7000 BCE. All these finds have challenged the view that agriculture spread from the north and that Chinese rice originated from India.

Other views about China’s prehistory also have been challenged. In July 1986 a discovery at Sanxingdui 三星堆, c. 1400–1000 BCE in Sichuan Province proved the existence in other parts of China of advanced Bronze Age cultures besides the historically documented Shang. Artifacts, such as sculptured masks and human bronze heads, showed a unique style and were of a level just as advanced as those unearthed at Anyang.

When the ban on Sino-foreign fieldwork was lifted, joint archaeological explorations were conducted for the first time since before World War II. A Sino-Japanese expedition, for instance, set out for Xinjiang Uygur Autonomous Region to search for early traces of civilizations along the Silk Roads and found Bronze Age cultures in the southern parts of the Taklamakan Desert. A Chinese-French team in the same area conducted several excavations at Yuansha gucheng 圆沙故城 between 1993 and 2005, a city that in the preliminary reports has been stated to be the oldest ever found in Xinjiang, dating back at least twenty-two hundred years.

Many sites and artifacts have been found throughout the country in recent years. The expansion of the Chinese economy and extensive infrastructure construction have led to numerous rescue excavations in the last thirty years. These in turn have led to an enormous input of new archaeological material. New university departments of archaeology have been set up throughout China. Specialized institutions, such as China’s first DNA research laboratory in Jilin, have improved the technological analysis of excavated remains. Other fields of archaeology, such as underwater archaeology, also have been introduced. The latter has been instrumental in the rescue of the late Song dynasty merchant ship Nanhai 1 南海一号, which sank eight hundred years ago in the South China Sea with bluish-white porcelain in its cargo. Found in 1987, the entire vessel was salvaged from the seabed in 2007.

Chinese architecture—from the Great Wall to the Forbidden City—has long distinguished itself from building traditions in other parts of the world. Its breadth of design encompasses not only individual buildings like pagodas, palaces, and temples but also cities, gardens, and tombs—complex interconnected structures built according to court-produced plans.

From as early as Neolithic times, wood has been a dominant material in Chinese aboveground construction. The timber frame is considered to be China’s major contribution to world architectural technology, and its design is unparalleled in its flexibility and ability to withstand earthquakes. Other important features of ancient Chinese architecture include the raised platform and the decorative roof.

The Chinese use of wooden support systems in architecture can be traced back about seven millennia to the mid-Neolithic period. The structure was formed by a system of interlocking wooden supports, employing mortise and tenon joinery. The load-bearing timber frame supported the structure while the walls were used to separate enclosures. The oldest example of this timber frame was discovered in Zhejiang Province at the Hemudu site, which dates to about 5000 BCE. Semisubterranean structures that utilized wooden beams and pillars to support thatched roofs have also been uncovered from the mid-Neolithic period.

One critical element of the Chinese wooden structure is the bracket set, or dougong—a group of wooden interlocking components that attached pillars and columns to the roof without the use of aids in joinery. Dougong became widely used by the Spring and Autumn period (770–476 BCE) and continued to evolve into a complex system of interlocking parts by the Tang (618–907 CE) and Song (960–1270) dynasties.

The dougong sits on top of a column and under a cross-beam and is made of a double bow-shaped arm, called a gong. The gong supports blocks of wood, called dou, on either side. The brackets are stacked in layers and support the load of the roof. Hierarchical restrictions in feudal China allowed the use of these brackets only in the most important buildings, such as palaces and temples. The more important the building, the greater the complexity and number of bracket layers.

Because the dougong structure allows the weight of the roof to be supported by pillars instead of walls, it is highly resistant to earthquakes. Where brick and mortar walls would collapse, the basic framework of the building would remain intact. Hence, it is said that “Chinese houses will stand even when their walls collapse.” These bracket sets have allowed many ancient buildings in China to survive for hundreds of years.

The use of rammed earth and unbaked mud bricks was also in use by the mid-Neolithic period. Layers of earth were pounded together to form foundations, walls, and alters. Sections of the Great Wall of China were built using layers of rammed earth. Homes were often built using sun-dried mud bricks to form walls that were then built around the wooden frame. Floors were made of pounded earth that was hardened through heating.
In traditional Chinese architecture, nearly every part of a building was decorated. In ordinary buildings, ceilings were often decorated using wooden strips that were covered with paper. Latticed ceilings were made using strips of wood or sorghum stems that were woven and attached to the beams. More elaborate ornamentation was reserved for the most important buildings, such as temples, tombs, and altars. As with other structural elements of traditional Chinese architecture, roofs and ceilings were constructed without the use of nails but were held together using bracket sets.

The Chinese architectural tradition can be separated into early, middle, and late periods. The early period stretches from Neolithic times through the Bronze Age (around 2000 BCE) to the period of disunion known as the Three Kingdoms (220–265 CE) and into the North and South dynasties (220–589 CE). The middle period begins around 580 CE under the Sui dynasty (581–618 CE) and continues through the Tang (618–907 CE) and Song (960–1279 CE) dynasties. Historians of Chinese architecture disagree on when the late period began. Many consider the period of Mongolian rule during the Yuan dynasty (1279–1368) to be a transitional period. The late period of premodern architecture is considered to have lasted from the fourteenth through the nineteenth centuries.

In this evolution, the years 1103 and 1734 stand out as benchmarks. Those are the dates when two complete and extant court-sponsored building manuals were issued: Yingzao fashi (Building Standards) and Gongbu gongcheng zuofa zeli (Engineering Manual for the Board of Works). These technical treatises provided architectural standards for builders, architects, craftsmen, and engineers. From these writings, it is known that even though general principles of Chinese construction changed little over long periods of time, there were specific differences between the construction of important, or high-ranking, architecture and more humble structures.

Three features distinguish the Chinese building tradition from those of most other parts of the world. First, Chinese architecture includes not only buildings such as pagodas and temples but also cities, gardens, and tombs. Second, traditional Chinese buildings were usually constructed as part of a complex of structures that were joined physically by covered walkways and spatially by courtyards. Third, the name of an architect was rarely associated with a building. Designs for palaces, cities, imperial monasteries, and imperial gardens were produced at court. The pay scale for workers and the allotment of building materials were standardized. Builders were craftsmen, and a modular system made it possible for a group of craftsmen and builders to erect a timber frame based on proportional units.

**Early Architecture**

Most of our knowledge of Chinese architecture before the first millennium CE has come from archaeological excavations. Some sites have been studied for nearly eighty years, such as Anyang, which served as the capital of the Shang dynasty (1766–1045 BCE) from approximately 1300 to 1050 BCE. Others have been discovered and excavated more recently. Several sites dating to Neolithic times...
have been uncovered, such as Banpo in Shanxi Province, Chengziyai in Shandong Province, Hemudu in Zhejiang Province, and Niuhuliang in Liaoning Province. One of the most impressive findings from these sites is that each, despite representing a different Neolithic culture, revealed common characteristics. For example, each included evidence of four-sided structures defined by exterior columns, a great hall or temple, platforms or walls made using the terre-pisé method (also known as the rammed-earth method), and each was probably enclosed by an outer wall.

From the Anyang site and two others in Henan Province, we know that Shang cities were enclosed by walls as long as seven kilometers around, that large structures may have been palaces, that residential buildings were constructed on raised foundations, and that tombs of immense proportions were dug underground and were faced with wooden walls. Buildings presumed to be funerary shrines or temples stood above ground on top of the burial chambers.

The earliest evidence of imperial gardens and pleasure palaces comes from the Zhou dynasty (1045–256 BCE). However, information about these gardens and palaces is known only through literary sources. Perhaps more importantly, the Zhou dynasty represented a crucial period in the history of Chinese urbanism. During this period, major cities and capitals were surrounded by walls. Many cities included a wall-enclosed palace city inside the outer wall. This feature was to become a trademark of Chinese imperial planning, preserved even in the last great capital, Beijing’s Forbidden City.

Zhou cities were laid out according to three distinct plans. One plan placed the palace area near the center of the outer wall, another located it in the north center, and a third put it adjacent to the outer city. This last type is sometimes referred to as a double city. The two walls often reflected more than one building period. Texts from the Zhou dynasty describe the ideal ruler’s city and ritual halls. The earliest existing remains of imperial ritual halls, however, are from the Han dynasty (206 BCE–220 CE).

Remains of aboveground buildings and extensive information about funerary architecture exist from the Qin dynasty (221–206 BCE) to the fall of the Han dynasty four hundred years later. The most impressive architectural achievement of the age, however, was the Great Wall. The history of the Great Wall begins in the Warring States period, a time of disunion in China when seven powerful states competed for control of the country. Most of these states built walls along their borders, where they stationed troops to defend against their enemies. At the time, the combined length of the walls totaled about 5,000 kilometers.

In 221 BCE, the ruler of the Qin state, Qin Shi Huangdi, defeated the other six states and unified the country. Known as the First Emperor, Qin Shi Huangdi ordered that the various sections of wall be connected and further sections built in order to strengthen his new rule and defend against invaders from the north. When the work
was completed, the wall stretched from today’s Liaoning Province in the east to Lintao, Gansu Province, in the west. Construction of the wall continued sporadically from the Qin dynasty through the sixteenth century.

During the Qin dynasty and before, the wall was constructed of local materials, often earth packed between board frames. As a result, the early portions of the wall did not include fortresses, and bricks were not used in the construction of gates. Large pieces of stone were also used to build sections of the Qin wall, and detritus was collected and used to fill the gaps between them.

Remains of the wall from the Qin, Han, and Zhou dynasties still exist in Dunhuang City in Gansu Province, Yulin City in Shanxi Province, and Baotou City in Inner Mongolia. Sections built by the Zhou during the Warring States period were constructed using stamped earth between wooden frames, and the layers of earth can still be clearly seen.

Most of the freestanding architecture that remains from the Han period is a form of gate tower called que. These multistory, narrow structures stood in pairs at the entrance to tombs and on either side of gateways to cities and palace complexes. They were also mimicked in structures atop the corners of walls that enclosed palaces and cities. Additional evidence of the que form is preserved in the many relief sculptures that once lined the walls of Han tombs, especially in the provinces of Sichuan, Henan, and Shandong. The form is also evident in tomb murals from almost every part of China.

The burial chambers of the Qin emperor and of the emperors and empresses of the Han dynasty remain unopened, but hundreds of Han tombs have been excavated. From them, archaeologists have learned that while common people were buried in simple pits, wealthy citizens, aristocrats, and members of the royal family were buried in tombs with as many as nine or ten rooms. These underground palaces were constructed of permanent materials, primarily brick and stone, and were dug deep in the earth to improve preservation. It is believed that the tombs were built in accordance with the forms of residential architecture that were employed above ground but without the use of perishable wood materials. From the tombs and replicas of architectural forms, archaeologists have learned that bracket sets, ceramic-tile roofs, and vaulted ceilings were in widespread use by the Han dynasty.

The last period of early architecture in China was one in which Buddhism, brought to China from India around the first century CE, was the main religion. The influence of Buddhism on architecture was apparent in the many temples and monasteries erected. For example, more than 1,300 Buddhist monasteries were built in the capital city of Luoyang during the period of Northern Wei rule (493–534 CE). Foundations are all that remain of those temple complexes, but other examples of Buddhist architecture from the third through sixth centuries survive in the form of pagodas, interior construction, and decoration of worship caves.

The earliest dated pagoda in China was built in 523 CE and stands at Songyue Monastery on Mount Song in Henan Province. Its twelve-sided shape and fifteen tiers of densely spaced eaves are unusual. The use of brick instead of wood in its construction had much to do with the endurance of this pagoda through the centuries. The single-story, four-sided pagoda at Shentong Monastery in Licheng, Sichuan Province, was built in 544. In general,
Chinese pagodas were four-sided in plan through the early years of the Tang dynasty. In profile they could be of uniform exterior dimension, as was the case with the pagoda at Shentong Monastery. They could also taper in perimeter from the base to the roof. Made of either brick or stone, the exteriors were decorated with columns, bracket sets, and roof eaves in imitation of wooden architecture. Pagodas of different sizes and shapes are also found inside Buddhist caves known as central-pillar caves.

Middle Period

The oldest extant wooden architecture in China is a Tang dynasty (618–907 CE) hall dated to 782. It is located at the Nanchan Monastery on the sacred Mount Wutai in Shanxi Province. Three other extant wooden buildings from the Tang period are also in Shanxi; one is on Mount Wutai and two are in the southern part of the province. The timber frame had reached full maturity by this time.

No palace buildings survive from the Tang. But excavations at the capital city of Chang’an (the largest city in the world in the eighth century with a population of more than 1 million) have been so extensive, and textual descriptions are so excellent, that the placement of every building in each Tang palace complex is known. Many have been reconstructed on paper.

The sites of the tombs of each emperor and empress of the Tang period are also known, and several of the monumental sculptures that lined the approaches to those tombs survive. Scores of tombs of Tang princes and princesses have been excavated, and many of these are satellites to the tombs of the emperors and empresses.

About fifty wooden buildings survive from the two centuries following the Tang dynasty, including several of the most extraordinary wooden structures ever built in China. The Liao dynasty (947–1125), established in northern China by the Khitan people, commissioned the construction of wooden pavilions and pagodas that used more varieties of bracket sets than ever before in a single structure. For example, the 67.31-meter pagoda at Fogong Monastery in Ying county, Shanxi Province is the tallest wooden structure in the world and employs fifty-four different types of bracket. It also exhibits a second feature that is characteristic of Liao wooden buildings: concealed interior stories that do not correspond to those visible from the outside. The pagoda shows five exterior stories plus a sixth set of roof eaves, but it includes four additional mezzanine levels on the inside.

The Liao built a variety of pagodas using masonry. Some had a base, shaft, and densely placed eaves similar to the pagoda dated to 523 at the Songyue Monastery on Mount Song. Others had a shaft and roof for each story. Most pagodas of the Liao and Northern Song (960–1126), the Chinese dynasty to the south of Liao, were octagonal in plan. Octagons and hexagons also became common shapes in the building of underground rooms in Liao and Song tombs.

Later Architecture

The modern period of Chinese architecture was ushered in by Mongolian rule. In spite of the ethnic background of the imperial family, most construction during...
the Yuan dynasty (1279–1368) followed Chinese building standards. More than 250 wooden buildings remain from the Yuan period. Among the most famous are a gate and three halls at Yongle Daoist Monastery in southern Shanxi.

The Forbidden City is the architectural masterpiece of imperial China’s last great age, the Ming (1368–1644) and Qing (1644–1912) dynasties. First and foremost, the Forbidden City was the home of Chinese emperors and the center of their universe. Its plan embodies the 2,000 years of architectural history leading up to it. The focus of the Forbidden City is the Three Great Halls, elevated on a triple-layer marble platform. The capital-I shape of the platform was reserved for China’s most eminent architectural arrangements. It is replicated directly behind the Three Great Halls, in the Three Back Halls, where the emperor and empress slept and where the empress held audiences. Surrounding the halls is an array of palaces, where every aspect of life—from the education of the princes, to the preparation of food, to palace intrigue—was carried out. Today, most of the Forbidden City is used as a public exhibition space to showcase former imperial treasures and to house offices of the Palace Museum. Directly in front, on ground once closed to public passage, is Tiananmen Square.

Many of China’s other architectural masterpieces of the Ming and Qing dynasties are in Beijing or its suburbs. Most important are the Ming Tombs, where thirteen emperors and their empresses are buried beneath circular mounds with ceremonial halls in front of them. Some of the ceremonial halls are raised on three-tiered marble platforms like the one under the Three Great Halls. The individual halls are also similar in form to the main halls of the Forbidden City.

Surrounding the Forbidden City were the suburban altars, epitomized by the Altar of Heaven complex. Its three main halls, arranged along a north-south line, were the locus of annual imperial supplications to heaven on behalf of the Chinese state. Circular in plan but surrounded by a four-sided enclosure, the Hall for Prayer for a Prosperous Year is the only Chinese structure with a three-tiered conical roof.

Qing imperial architecture extended beyond Beijing to include five summer palaces north of the Forbidden City, the Eastern and Western Imperial Tombs in Hebei, a palace and tombs in Shenyang in Liaoning Province, and a summer palace in Chengde, Hebei Province.

The later periods of premodern Chinese history were also times of architectural accomplishment outside the imperial sphere. Private gardens of wealthy citizens, especially in southeastern cities such as Suzhou and Yangzhou, have attracted international attention.

Contrasting with the poetics of landscape architecture are the residential styles of China’s populations on the fringes of the empire—flat-roofed houses designed for the mountainous settings of Tibet, tents of the Mongolian grasslands, houses raised on stilts in the humid swamplands of the south, circular houses of the Hakka in Fujian Province, and two-story houses with sky wells in the center in Anhui Province.

Until the last half of the twentieth century, when modern architecture was imposed through city ordinances and national laws, Chinese architecture resisted modernization. Even to this day, Chinese-style roofs cap schools, hospitals, and government offices that are otherwise made of reinforced concrete. Public buildings retain courtyards at their entrances. Hotels and restaurants relinquish precious space to make room for miniature replicas of Ming gardens. And the Forbidden City has remained the immutable focus of Beijing and a symbol of all of China.

Further Reading

From the nineteenth century to the present, Chinese art has undergone drastic changes that mirror earthshaking internal challenges to tradition and reflect as well a myriad of modernizing forces, many foreign, that have penetrated country and culture. Since 2000, Chinese artists have rapidly (if belatedly) garnered kudos (and high prices) in the world art market, a testament to their creativity and innovation.

Most Westerners think of Chinese art in its most traditional format: as ink painting created with brush strokes that look similar to those used in Chinese calligraphic writing. But in the nineteenth century, notions of Western modernism began to invade traditional Chinese culture. Scientific drawing, French Academic realist oil painting, and new art materials and technology challenged the tradition. Chinese reformers and artists alike undertook many aspects of modernist experimentation from the mid-nineteenth to the mid-twentieth centuries.

In 1949, when the Chinese Communists were victorious, art was designated to serve the people and the revolution. Soviet-style socialist realism became the official style. After Mao Zedong’s death in 1976 and the end of the Cultural Revolution (1966–1976), China changed into a more open society and the government eased some of its cultural control. Artists revived ink painting and explored all the international styles, including performance and new media.

Nineteenth-Century Origins

To understand the cultural changes that have influenced Chinese artists, one must briefly review the dark period that began with foreign invasions and civil wars in the mid-nineteenth century. After Britain’s victory in the First Opium War of 1839–1842 (a second war would follow from 1856 to 1860), the defeated Chinese conceded five treaty ports where foreigners could live and trade. In 1864, after a prolonged and devastating civil war conducted under the ominous presence of Western troops, the Qing imperial government forces finally triumphed over the Taiping rebellion. Chinese felt pressure after the French conquest of neighboring Vietnam, and Japan defeated China in 1895. The final blow came in 1900 when legions from the foreign treaty ports defeated the imperial troops in the Boxer rebellion.

The 1842 opening of treaty ports had allowed new influences to enter through the media of books and magazines, new technology and materials, and new visions of what the world looked like to people outside of China. Photography and various printing techniques were introduced, including Japanese-style woodblock printing, all of which were quite different from methods that had previously been available in China.

The tradition of Chinese painting in the nineteenth century looked back to the Ming-dynasty painter Dong Qichang (1555–1636), who taught a particular formula that
focused on preserving images and values of the cultivated scholar. The student was to emulate his master’s work and begin by copying old Chinese paintings; such paintings were typically brushed in ink, and they depicted small figures of a scholar and friends viewing nature from a grass shack beside a steam and mountainside. Not until the aspiring artist was fifty or older was it considered possible for him to create his own style.

Traveler in the Mountains, by Dong Qichang (1555–1636). Much Chinese painting in the nineteenth century relied on the teachings of Ming-dynasty painter Dong Qichang, who advocated preserving the values and traditions of the cultivated scholar. Dong’s paintings often depicted small figures of a scholar and friends viewing nature beside a steam and mountainside. NATIONAL PALACE MUSEUM, TAIPEI, TAIWAN.
Many intellectuals found nineteenth-century ink painting on silk and paper to be stagnant. Paintings of idealized mountain landscapes were thought to be without energy and originality. This idyll no longer represented reality in nineteenth-century China. The multiple realities of China—from the increasingly international treaty-port cities to the seemingly pristine countryside—would all be caught up in great change. But the changes to Chinese traditional painting were subtle in the beginning, introduced one small step at a time.

Only lightly tinted watercolors were used in traditional ink paintings; brilliant colors were excluded. Confucian values taught that red, yellow, green, and blue were the only acceptable colors for decoration; any color that was mixed and had an offbeat hue, such as lavender or pea green, was considered deeply suspicious because of the potential emotional response it might evoke. One innovation brought to Chinese painting at this time was a vibrant red pigment called Western red—the name, of course, reflecting the beginnings of foreign influence.

Chinese merchants, who were prospering in the treaty ports, became new art patrons. Their taste was not as refined as that of the old elite who favored monochrome or only very pale tinted paintings, and they welcomed the new decorative and colorful paintings that were beginning to emerge.

Photography, in the form of print materials, magazines, newspapers, and pictorial calendars, made a significant difference in enlarging the Chinese vision. Landscapes and portraits of people captured through the camera’s lens became favorite subjects to replace traditional paintings. Photography, as well as Japanese woodblock prints by the famous Utagawa Hiroshige, introduced compositions with newly angled views and perspectives that gained artists’ attention. Photographs were used as backdrops in portrait studios and influenced stage-set design. Slick advertisements in print and on the boxes and wrappers of all kinds of products that poured into the treaty ports—from cigarette cards to cosmetic jars—afforded great visual variety and were ragingly popular. Lithography offered new possibilities for reproducing art and, especially, calligraphic writing, an important component in painting and other art forms. Cartoons and serial stories had new life and flexibility, and were embraced by the artists dealing in a new visual world.

Historical illustration of young Chinese man painting in the Western style.

Committed to Change

Traditionally the Chinese had always considered themselves to have the highest level of cultural achievement and to be the most powerful nation in the world. But by the late nineteenth century, many Chinese intellectuals realized that their civilization was not the center of the universe. (Zhongguo, Chinese for China, literally translates as Middle Kingdom.)

The most persuasive case for reforming the arts was that Western-style painting was scientific. It introduced precise drawing of the objective world using single-point perspective, shading to reveal volume, and a single light source. This kind of representation defined buildings and machines, and was the visual expression of modern
science. Reformers introduced Western-style perspective drawing, mechanical drawing, and drafting into school curricula at the end of the Qing dynasty (1644–1912). The Chinese dynastic system ended when the imperial troops of the Qing were defeated by the revolutionary Nationalist forces in 1911; the Qing emperor abdicated in 1912. The victors established the Republic of China (1912–1949), and the new government was committed to change. Cai Yuanpei (1867–1940), the first minister of education, called for major educational reforms and championed aesthetic education. Chinese art underwent great changes during this period while still conserving and protecting many traditional elements such as ink painting.

At the beginning of the twentieth century, the first art teachers were Japanese who came to China to teach new techniques, especially technical drawing in pencil and charcoal. Included were design, plane- and three-dimensional mechanical drawing, perspective, and forms of projective geometry.

Many Chinese artists studied in Japan at the end of the nineteenth and beginning of the twentieth century and were influential in the changes. Among the earliest were those from Guangzhou (Canton)—Gao Jianfu (1879–1951), Gao Qifeng (1889–1933), and Chen Shuren (1884–1948)—who studied realism and sketched from nature in the style of Nihonga painting in Kyoto. They brought back a new, studied, and more realistic vision of landscape and bird and flower paintings in ink and watercolors, the traditional materials. A circle of artists gathered around them and was called the Lingnan School.

**New Schools**

In November 1912, after the establishment of the Republic of China, teenaged Liu Haisu (1896–1994) and two others founded the first modern art school to teach oil painting in China, the Shanghai Art Institute. Liu was a pioneer educator who welcomed both female and male students, and he introduced the practice of sketching directly from nature as well as from human models. Because it was then considered scandalous to sketch nudes and exhibit the paintings, the local warlord threatened to close the school and arrest Liu. But Liu carried on an intense campaign to legitimize his school’s practice and exhibition policy and in the end won, probably because the Nationalist forces of Chiang Kai-shek took over the area. Liu had a most important ally, scholar/modernizer Cai Yuanpei. Liu Haisu eventually traveled to Europe to exhibit his work and lecture; while there he admired and was influenced by the brilliant coloration of the post-Impressionists.

A number of traditionalists, however, such as the early twentieth-century stars Zhang Daqian (1899–1983) and Huang Binghong (1864–1955), stuck to the old ideas, using ink and paper. But they called on painters to be inventive and display a new energy within the old parameters. Huang explored a deeper level of density in black ink, creating a new, intense mood. Zhang used colors with an inventive boldness. Zhang traveled abroad and went to northwestern Gansu Province in 1942 during World War II, which the Chinese called the anti-Japanese war (especially in the context of their own War of Resistance...
against Japan, 1937–1945). There he copied some Buddhist cave paintings in styles and techniques from the fourth to twelfth centuries, which served as inspiration for generations of new Chinese artists in the late twentieth century.

Pan Tianshou (1898–1971) and Qi Baishi (1864–1957) were both influential in prolonging the popularity of traditional methods, yet each had his own view of how to go about it. Pan’s bird and flower compositions, painted on a new monumental scale never previously attempted, would compete in size and importance with the large official oil paintings. Qi, whose first career was carpentry, adopted humble subjects traditionally ignored by the literati elite—garden vegetables, fish, shrimp, and baskets—often painted with the brilliant red thought to be vulgar by the literati. His paintings were very popular.

Modernism in China

Not surprisingly, great interest in Modernist art began to blossom in 1919, the same period that the May Fourth literary movement flourished. Many Chinese artists returned from Japan and Europe where they had learned about the newest trends of Impressionism, post-Impressionism, Constructivism, Cubism, Fauvism, Surrealism, Expressionism, Futurism, woodcuts, and graphic design.

Few paintings produced in those Modernist styles during the 1920s and 1930s have survived. Some were burned when the Japanese bombed Shanghai. Others were lost when refugees escaped to Chongqing, the wartime capital (1939–1945), or were destroyed by Red Guards during the Cultural Revolution. Others simply perished without proper storage.

Shanghai was the center of the Modernist movements in the 1920s and 1930s. Guan Liang (1900–1986) returned from Japan using Fauvism in his artistic explorations. Pang Xunqin (1906–1985) returned from France to Shanghai creating Surrealist compositions. They and other Modernists formed the Storm Society and Chinese Independent Art Association where they could meet, discuss, and exhibit art. In 1929 the government created the National Hangzhou Arts Academy (now called China National Academy of Art) and appointed the French-trained Lin Fengmian (1900–1991) as its head. Lin felt that artists should choose their own artistic path, which was a departure from the teachings of Xu Beihong, who wanted his protégés to follow his style.

Chinese Modernists of the 1920s and 1930s communicated with Europeans, which fueled the movement, but those lines were cut when the artists fled to western China during World War II. The Communist Party followed Stalin’s official line on Modernism as being capitalist and corrupt: Modernist artists’ led bourgeois or bohemian lives, the policy stated, thus their styles were morally unworthy for the ideals of socialism and therefore must be excluded.
Socialist Realism

On 1 October 1949, Mao Zedong proclaimed from the top of the Tiananmen gateway to the old Imperial Palace that “China has stood up.” The founding of the People’s Republic of China began a new era of Chinese Communist rule, one in which art would serve the state, to quote Lenin, “like a cog in the wheel of revolution.”

In 1942, when Mao was in his wartime camp in Yan’an, he gave “Talks on Art and Literature” that set the artist’s mission. Artists must live among the peasants, he said, and “feel dung between their toes.” Only then would they undergo a class change and be able to communicate with the masses. They must paint the stories of the heroic revolutionary struggle and the triumphs of the new society.

How to achieve this new revolutionary art was an evolving strategy created by the propaganda department of the Communist Party. The first experiments were with dynamic cartoon styles, inspired by Chinese folk art, which were painted in the national-style guohua, ink and colors on paper. But soon the more dramatic socialist-realist oil-painting style of “Big Brother Soviet Union” was adopted. The style was descended from European Grand Manner compositions; nobles were re-costumed from the cannon of revolutionary art. Religious art was considered superstitious, and some commercial art was condemned as pornographic.

Within the new media two print styles that affected change surfaced in cartoons and woodblock prints. Both were used to express disgust with a corrupt republican government that did not stand up to the invading Japanese, or help the millions of refugees, or stop its troops from looting and raping local peasants. The famous writer Lu Xun (1881–1936) encouraged the woodcut artists, who were deeply influenced by the German Expressionists and Kathe Kollwitz (1867–1945). Among the many brilliant Chinese woodblock artists, Li Hua (1907–1994) created powerful prints showing the suffering and frustration of the Chinese people; produced in multiple, they functioned as Communist propaganda handbills. These artists and cartoonists would play a major role as the Communist Party defined the new official Chinese style after 1949.

and transformed into giant workers, peasants, and soldiers breaking the chains of capitalism.

Chinese art histories claim Xu Beihong’s painting as the source for the official state socialist-realist style adopted in 1949, thus downplaying the obvious Soviet influence. The influential Xu Beihong (1895–1953) won a government scholarship to study in France in the 1920s and became an accomplished French Academic–style oil painter, totally ignoring the Western Modernist explosion that surrounded him. He devised the new style he advocated, a technique of ink painting using deep space perspective and foreshortening, to create his famous horses and giant peasants. Ink painting was revitalized, infused with realistic strength. Xu’s personal advocacy of the style, his presence as head of the Beijing Art College (which became the Central Academy of Fine Arts after 1949), and his friendship with Zhou Enlai were all factors in elevating his painting theories and style. After his death in 1953, he was officially hailed as the creator of Chinese socialist realism.

An example of official revolutionary oil painting was Dong Xiwen’s (1914–1973) *Founding of the Nation* (1954) showing Mao atop the balcony of Tiananmen Square as he established the People’s Republic. It became an iconic socialist-realist work. The new leadership was lined up on the side of Mao in a dramatically arranged composition inferring infinite control and a great future. The painting was widely reproduced for propaganda. But within five months one of the men in the leadership was purged, and Dong had to revise the canvas to eliminate the offender’s image. (Leadership purges would continue throughout Mao’s tenure. In 1980 a copy of the original made from a print was painted by Zhao Yu [1926–1980] and Jin Shangyi [b. 1938] to restore the original members.)

**Wang Dong Ling, with his painting *Chinese Art Meets West (Twin Fish)*.**

PHOTO BY JOAN LEBOLD COHEN.
Traditional ink painting, with vague landscapes, birds, and flowers, was out of favor in 1949. It was deemed reactionary and linked to feudalism and the old society. Not surprisingly, many ink painters fought passionately to restore its position, and by 1957, when the leadership became increasingly disenchanted with Khrushchev and the Soviet Union, guohua regained status. The compositions retained the socialist-realist formulae, but ink and watercolor was the medium. The talented, old-time revolutionary Shi Lu (1919–1982) created Fighting in Northern Shaanxi (1959) in a reprogrammed ink-and-watercolor style. A small but empathic figure of Mao stands triumphantly peering over a severe rocky mountain dramatically bathed in a revolutionary red-washed landscape.

During the Cultural Revolution (1966–1976), Mao’s wife Jiang Qing became China’s artistic czar, and she gave an emphatic boost to the socialist-realist style. She called for dramatic theatrical-type compositions that showed glowing heroes overcoming darkly cringing evil spies and counterrevolutionaries. The heightened glory of the revolution was meant to be evoked with strong forms and red, bright and shining; gray tones and any ambiguity were excluded. A vastly popular image of that time by Tang Xiaohu (b. 1941) and Cheng (Li b. 1941) was titled Follow Closely Our Great Leader Chairman Mao, Ride the Wind, Cleave the Waves, Fearlessly Forge Ahead (1972). Larger than life, Mao waves vigorously after his swim across the Yangzi (Chang) River amidst a regatta of red flags. This served to document Mao’s vigor and ability to rule China.

A New Generation
Experiments

The death of Mao in 1976, the trials of the Gang of Four, and the new leadership of Deng Xiaoping changed China. In 1979 the country saw a de-emphasis of the class struggle and new policies focused on economic development toward a market economy, which would transform the art establishment. The government was no longer the sole patron, and its iron grip was slipping away. Young artists, such as Chen Yifei (1946–2005) and Han Xin (b. 1955), pushed the official party-line limits of style and content.

In Looking at History from My Space (1979) Chen Yifei abandoned the dramatic compositional buildup of the old socialist-realist, proscenium-stage style and painted himself—with his back to the viewer and his empty studio chair off to the side—observing cinematic episodes depicting events from Chinese history in the early twentieth century. The result is a portrait of an individual artist who in the previous era would have been assigned the role of a proletarian art worker among the masses—and who, it seems, now separates himself from the events and the glorification of them.

In late September 1979 some young artists who called themselves “Star Stars” created work in the previously taboo abstract styles, with political and sexual content. They hung an unauthorized exhibition outside the National Art Gallery for two days until the police removed it. This was the beginning of experimental art in a changing China. One member of that group, the young Ai Weiwei (b. 1957), was a profound devotee of Marcel Duchamp and the Dadaists, and he consistently made jokes about the establishment. Ai would go on to become an architectural consultant in building the Bird’s Nest Stadium for the 2008 Beijing Olympics.

The 1980s was a decade of change, although many ink painters sought to revive once more the primacy of traditional ink painting with vague landscapes, birds, and flowers. But many young artists broke out of the official approved styles into experimental modes. Two outstanding artists who worked with ink created new formulae for handling calligraphy, traditionally considered a sacred cannon of Chinese writing. Gu Wenda (known in the West as Wenda Gu) partially erased character strokes in his calligraphic pieces, and Xu Bing created printed books with two thousand new characters that have no meaning. Each was toying with the pillars of the established culture, suggesting its impotence and irrelevance.

In 1989 the National Art Gallery invited Gao Minglu, a curator interested in experimental art, to mount an exhibition. Huang Yongping showed a blob of mushy paper on a block titled The History of Chinese Art and the History of Modern Western Art after Two Minutes in the Washing Machine. Wu Shanzhuan sold shrimp at a food stand in order to express his “shock” that China’s new market economy was so contrary to Maoist principles. But the most dramatic piece was performed by Xiao Lu, who reproduced two phone booths side by side inhabited
by male and female dummies talking. Xiao had a gun and shot the figures in the phone booths with live ammunition. The police arrested her and her boyfriend, a collaborator, and shut the show down. This was less than six months before 4 June 1989, when the students leading the Democracy movement, which called for end of official corruption and more voice in governance, were crushed at Tiananmen Square.

Performance Art

Performance had become a favored method of expression by 1989, and those Tiananmen events were documented by film and video, media that would become the cornerstone of a new visual culture in China. Pioneering video artists Zhang Peilei scandalized his audiences by washing a chicken repeatedly for a half hour. In Brooklyn

Han Xin, seated in front of his painting *Crucifixion*, 1991. PHOTO BY JOAN LEBOLD COHEN.
Sky: Digging a Hole in Beijing (1995), Wang Gongxin commented ironically on the Western fantasy of digging one’s way to China. He placed a video monitor in a deep, 3-meter-wide hole near his residence in Beijing from which he played footage of the Brooklyn sky. Video artists from Shanghai, such as Yang Fudong and Yang Zhenzhong, have produced parodies of pretentious intellectuals, imitating old style literati and other provocative themes.

In the 1990s Guangzhou’s Big Tail Elephant group comprised some very talented artists who poked fun at the folly of officedom. Lin Yilin created a video piece, Safely Maneuvered Through Lin He Street, acting out the irrational nature of traffic, barriers, and drivers—official rules and noncompliance resulting in nonsense.

High-tech photography arrived in China in the early 1990s and transformed the use of the medium, previously relegated to portraiture and posed propaganda scenes. Experimental artists, such as Zhang Huan, had himself photographed and filmed while he sat in a village latrine covered in honey and fish oil, an inviting feast for flies. This stunning anti-official act of art, which commented on Zhang’s personal living conditions, was photographed by several of this new breed of photographers, including Rong Rong and Xing Danwen. Shao Yinong and Muchen have photographed derelict official meeting halls all over China, preserving in pictures of these abandoned buildings their uncompromising beauty and a nostalgia for the time when they were vital centers of Communist Party power. It was in these halls that the class struggle was acted out.

Pyrotechnics, which are powered by explosives invented by the Chinese in the ninth century, are endemic to Chinese emphatic moments. Cai Guo-Qiang grew up among the makers of fireworks in southern Fujian Province and has pioneered the use of explosives to create works of art. His pyrotechnic creations have been set off all over the world against the backdrops of sky, landscape, earth, architecture, and even paper—his earliest experiments with gunpowder in his drawings led to his explorations with explosives on a larger scale—and all have been recorded as video performance.

In 1995, for the International Women’s Conference, Lin Tianmiao created Proliferation of Thread Winding, a bed with hundreds of weaving threads attached like a glorious full skirt. In the middle of the bed, an elongated oval shape suggesting the female sex organ was filled with densely packed protruding iron needles. A video of the artist winding the threads was projected on the pillow. Lin invokes the mythology of the Chinese mythical progenitors, when the weaving maiden crosses the Milky Way to meet the herd boy, as well as the female’s primary reproductive function.

**Realism, Pop Art, and the New Century**

Amidst all the experimentation during the decades after Mao’s death, the mainstream teaching at China’s art academies continued to focus on French Academy–style realism, drawing from life to get accurate images of the subject. Although experimental artists have totally rejected the practice of this art, it continues to be a basic reference for many. Chen Danqing grew up and was mainly self-taught during the Cultural Revolution until he entered the first reopened class in 1979 for a master of arts at the Central Arts Academy. His work was admired for its unenhanced, straightforward depictions of people, without the official propaganda pitch. He greatly admired Rembrandt and Holbein. Another realist painter of that generation, Liu Xiaodong, also paints ordinary folk but usually with a stinging, acidic comment on naughty youth and corrupt officedom. Yu Hong paints her autobiography and the story of other women in a realist idiom. In the years after the 1989 Tiananmen riots, Fang Lijun painted himself, his bald head echoing an open-mouthed scream to no one. The image has a monumental intensity.

Zhang Xiaogang, an artist whose work has been represented and auctioned by some of the world’s most renowned galleries, paints his family in Bloodlines, a series of primarily black and white realist group portraits set against a backdrop of surreal clouds or seemingly covered by fine mist. On each face one colored splotch of paint suggests some kind of birthmark or skin affliction. The figures are linked to each other by thin red veins, the bloodlines that are the conduits between generations. In some works of the series Zhang uses the bloodlines to link the figures’ hearts to tiny TVs, speakers, radios, or books. Thus the paintings can be interpreted to reveal their subjects’ individual dysfunctions through the skin discolorations and to comment on the
collective heritage they are fed through their cultural surround.

Realist training also lies below the pop art surfaces of Yue Minjun’s laughing faces meant to mock the establishment. His simplified figures could just as well cry out in anger and frustration, but he makes his point by allowing them laugh. Qi Zhilong also comes from this realist background into the pop art realm, with his “sweet young things,” pig-tailed women dressed in khakis that suggests the military garb worn during the Cultural Revolution. They are the fresh faces of advertising and film who could invite a world of consumption or lead a life of service. Surely these virginal portraits were meant to invite prurient thoughts.

Wang Guangyi paints in another pop art vein in the Great Criticism series. He creates boldly colored dramatic socialist-realist compositions in which groups of muscular, oversized workers march with pens instead of guns and are juxtaposed against corporate logos from international giants such as Coca Cola. He advertises what he sees as the sellout of the proletariat to capitalism. Yet in other pop views, Li Shan’s Rouge series of the 1990s presents a pinky-red setting for a suggestively feminized Mao holding a lily in his mouth. At the same time, Yu Youhan painted the Communist leadership as faceless cutouts made from charming folk textiles. The three Luo brothers, originally from Guangxi province, have produced a unique and garish...
pop style of old and new, using traditional New Year’s babies, for instance to promote McDonalds’ hamburgers and Coca Cola. Their medium is collaged paper that is lacquered on wood.

Sculpture

Sculpture is a relatively new medium to the Chinese art scene. Two outstanding practitioners are Sui Jian-guo and Zhan Wan. Sui has produced breathlessly militant and triumphant socialist-realist groups of figures, according to the Maoist cannon calling for the glorification of workers, peasants, and soldiers. But he also has produced fire-engine-red fiberglass Dinosaurs in sizes from tiny to enormous, and appropriated parts of Mao’s imagery (and his closet), such as the Mao Jacket, the Shoes (are they filled with clay?) and the Left Hand for that medium as well. Zhan Wan is the favored traditionalist because he reproduces in stainless steel the weirdly shaped and pitted stones featured in Chinese gardens. The shiny silver material puts the sculpture in the twenty-first century, but its image recalls old Chinese culture. This was the goal of the modernizing reformers a hundred years ago.

As China’s economic success in recent decades has lead to a renewed leadership role in world affairs, so too have its artists taken a new place on the world stage. Their creations have marched into the forefront of international markets. Beginning in the year 2000, when China’s world image as a great power became internationally acknowledged, its artists began to make an impact in the world art market. By 2008, auctions in Hong Kong and New York sold work by a small group of artists like Zhang Xiaogang and Cai Guo-qiang for more than two million dollars, with other Chinese artists commanding increasingly high prices. The speed of this leap from domestic to global in the early years of the new millennium is an affirmation of China’s creativity and innovation. Even if belated, this recognition in the art world has been welcomed by the Chinese, as they achieve a difficult feat: to create new art is both international and truly Chinese.

Artifacts from Chinese history were preserved in Chinese personal and court collections prior to the eighteenth century. After that time foreign contact, wars, and social upheaval meant removal from China and destruction of artifacts. Since Mao’s death, Chinese officials have sought to recover Chinese cultural artifacts and to preserve them from pressures of modernization and an expanding population.

China’s seven thousand years of cultural and historic artifacts represent the development of one of the world’s ancient cultures, but these artifacts have been at risk for many reasons. Age is an obvious threat, but expropriation by foreigners, political upheaval, the illegal sale and export of antiquities, and nature itself have put the physical artifacts of China’s history at risk. Only recently has the Chinese government begun to fully address the need for preservation of these artifacts and historical sites.

Dynastic Period

The emperors of the Tang 唐 (618–907 CE), Yuan 元 (1279–1368), Ming 明 (1368–1644), and Qing 清 (1644–1912) dynasties valued relics and artwork and kept these items for the use by special members of their courts. As early as the Song dynasty 宋朝 (960–1279), libraries for the collection of books had been established. Such collections were examples of the wealth of the Chinese empire, and also served to provide the educational materials necessary to provide the opportunity of education for purposes of social advancement within the Confucian meritocracy.

The Ming dynasty enjoyed great prosperity acquired through the Tributary States system and trade. The Ming was the first regime encountered by European explorers and traders, and most Chinese trade with these Western countries was in commodities (silk, cotton goods, tea, and ceramics). Because the Western traders were limited in their commerce, widespread expropriation of Chinese artifacts did not take place at first. Many of what are now seen as valuable artworks (Ming vases, etc.) were, in fact, common trade goods.

In the seventeenth century, art collection by the Chinese elite had become common. This was not done for purely aesthetic reasons; in the Chinese cosmological view of a universe based on "circular time" which repeats itself, possession of artwork from earlier dynasties gave the collector a link to the earlier era. Furthermore, the possession of an artifact owned by earlier owners could hold as much meaning as the object itself. This is similar to the quasi-religious view that an object (icon or talisman) would receive some additional meaning from an external source rather than simply having its own intrinsic value. This was evident in the Qing dynasty when replicas of artwork were common; even though the replicas were of superior quality to the original pieces, the originals were valued because of the qi 氣 (life force) they held.
As the European powers undermined Chinese authority in the eighteenth and nineteenth centuries, the Western desire for fine Chinese goods increased, and more of them were taken out of the country. To the Westerners this was simply trade in another commodity, not different from much of the other expropriation which has filled European and American museums and private collections. While this was a continuation of the superior status that Westerners felt they had, it would actually help to preserve much Chinese art and artifacts from the destruction they might have faced in the twentieth century.

Republic of China

The late nineteenth and early twentieth centuries were violent for China. Following a military defeat by Japan in the First Sino-Japanese War of 1895–1896, the Chinese government had to deal with the Boxer Rebellion against foreigners, the subsequent humiliating Boxer Protocol that required China to pay reparations to those foreign countries, a rising nationalist movement led by Sun Yat-sen, and subsequent military action to suppress the feudal actions of warlords in northern China. Occupation by Japan followed, and, before the twentieth century was half over, a civil war ensued as well. Cultural upheaval was capped by the Cultural Revolution, during which destruction of pre-Mao artifacts was accepted as patriotic.

Chinese Civil War

The greatest threats to Chinese art and artifacts came with the general destruction resulting from the Japanese invasion of 1931 and the subsequent periods of war. During the Chinese Civil War (1945–1949), the Nationalist leader Chiang Kai-shek had many of the greatest classical treasures removed from museums on the mainland and taken to Taiwan for “safekeeping.” The government in Beijing continues to see this as a theft of cultural antiquities; the government in Taiwan counters that if the pieces had not been removed from the mainland, they might have been destroyed during the Cultural Revolution (1966–1976). In any case, much of the greatest artwork created in China is held in the National Palace Museum in Taipei, Taiwan.

The claim that the artifacts might have faced destruction is a valid one. Although a State Bureau of Cultural Relics had been established by the victorious Communist government in November 1949, only superficial attempts at preserving historical sites and artifacts were made. The thirty-three sites identified under the Provisional Regulations on the Management of Heritage Conservation of 1961 were “revolutionary sites and buildings to commemorate the revolution.”

Cultural Revolution

The social upheaval from 1966 to 1976, which resulted from an extreme antiforeigner, anticlassical, and pro-Mao
viewpoint, was directed at placing Chairman Mao Zedong and his political philosophy above all others, including those of classical China. At the direction of the Gang of Four, which included Mao’s wife Jiang Qing, much of this was done through the destruction of historical and cultural artifacts that did not reflect Maoist thought. Items which reflected the “Four Olds” — old customs, old culture, old habits, and old ideas, were destroyed to keep them from corrupting the new direction of Chinese politics.

Post-Mao Era

Following Mao’s death in 1976, Deng Xiaoping sought to renew Chinese pride in their society by allowing a resurgence of traditional forms of art, including Chinese opera. The destruction of artifacts during the Cultural Revolution was seen as an attack on Chinese culture, and renewed efforts to preserve what was left were undertaken.

The post-Mao era has brought about the establishment of the State Administration of Cultural Heritage under the Ministry of Culture whose function is to identify and protect both movable and unmovable historic items and sites. In 1982, China issued the Law of the People’s Republic of China on the Protection of Cultural Relics, which was revised in 2002. Despite these administrative movements, the protection of historic Chinese artifacts is underfunded given the hundreds of thousands of sites and items that require protection.

One of the greatest regions under threat of destruction or theft is the area of the Three Gorges Dam, a massive engineering project to build a hydroelectric facility and inland waterway stretching westward from Hubei Province to Chongqing on the Yangzi (Chang) River. Hundreds of historic sites...
that will be flooded by the project, such as monasteries, cemeteries, and villages, have been identified, but funding for their relocation has been insufficient to protect them. Many of these sites have been looted, with their contents being sold on the black market.

One non-governmental effort to protect and reclaim historic artifacts from China is the Lost Cultural Relics Recovery Program, a non-governmental organization (NGO) under the auspices of the China Foundation for the Development of Folklore Culture. This group attempts to find and purchase historical items taken from China by foreigners. This movement has goals similar to that of Greece in trying to reclaim the marble sculptures taken from the Parthenon which are currently on display in the British Museum. However, because of the high profits which might be gained on the black market, some preservationists fear that offering to purchase artifacts taken illegally might encourage even more illegal trading.

Another aspect of artifact preservation is that of buildings and neighborhoods in historic cities. The movement for economic modernization has placed old, unused buildings at risk in areas scheduled for modernization. Chinese shikumen 石库门 (row houses) in cities like Shanghai are not truly traditional, but were built in the early twentieth century as housing for the growing population in major cities. Because they are generally small and low (one or two stories), they occupy land which could be used more productively for high-rise buildings. In Shanghai, some of the shikumen neighborhoods have been converted into Western-style restaurants and other commercial establishments, preserving the exteriors of the buildings while making more profitable use of them.

In May 2008, the Chengdu 成都 earthquake in Sichuan Province 四川 damaged hundreds of sites and artifacts, including the famous terracotta warriors at Xi’an 西安. One outcome of this cultural damage, as well as the damage to other structures, has been a greater commitment by the Chinese government to establish better construction standards for risk abatement.

From acts of nature, foreign expropriation, purposeful destruction, illegal sale and export, to the needs of an expanding population, ancient Chinese artifacts face many threats. Recent governmental and nongovernmental groups have attempted to develop an official structure to preserve and restore China’s cultural heritage.

Asian Games

Yàyùnhuì 亚运会

The Asian Games bring together athletes from Asian and Middle Eastern nations every four years to compete in conventional Olympic sports, as well as traditional regional and national sports. China and Japan dominate the events, which often serve as practice rounds for the Summer Olympics. China first hosted the event, the eleventh Asian Games, in Beijing in 1990.

Founded after World War II on the Olympic ideal of fostering peace and cooperation through sports, the Asian Games host competitions among Asian and Middle Eastern countries. The athletes compete in conventional Olympic sports, as well as traditional regional and national sports. China and Japan dominate most high-profile events, which increasingly function as preparation and proving grounds in years between Summer Olympics.

Japan won the overall championship in the first Asian Games (which had no Chinese participation) and all subsequent games up to 1978, with China the perennial winner since 1982. Taiwan’s entry as the Republic of China caused considerable controversy from the 1960s on. The controversy subsided only with the People’s Republic of China’s admission to the Olympic Games and an agreement whereby Taiwan would compete as the Chinese Taipei team.

China first hosted the event, the eleventh Asian Games, in Beijing in 1990, showcasing the city’s ability to host a major sports event. In spite of Beijing’s failed bid to host the 2000 Olympics, the Asiad helped lay the foundation for later success in landing the 2008 Olympics. China will host the sixteenth Asian Games, scheduled for 2010 in Guangzhou.

What has become Asia’s largest sports event has antecedents in earlier regional meets, notably the Far Eastern Games, initiated in Manila in 1913 and lasting through ten iterations to 1934, with hosting rotating among the Philippines, Japan, and China until the games succumbed to the expanding war in the Pacific in the late 1930s. The inaugural Asian Games were staged in New Delhi, India, in 1951, with eleven countries (not including China) competing in six sports—athletics, aquatics, basketball, cycling, soccer, and weightlifting. Although membership has fluctuated, the scale of the event has grown steadily, with the fifteenth Asian Games, held in 2006 in Doha, Qatar, drawing forty-five countries to participate in thirty-nine sports. As anticipated, China won the most medals, 316, with Japan winning 198 and Korea 193.

Planning has been periodically disrupted by disputes among member countries, leading to relocation but never cancellation. Other controversies have included Arab nations’ opposition to Israel’s participation, resulting in Israel being excluded (and redirected to European competitions); and admission of the former Soviet republics of Kazakhstan, Kyrgyzstan, Uzbekistan, Turkmenistan, and Tajikistan over some members’ objections. The Asian Games’ hallmark today is diversity: Christian, Muslim, Buddhist, and Hindu athletes mingle with nonreligious athletes; medal hopes come from highly developed
countries and poor ones; and conventional Western sports such as basketball, gymnastics, and swimming take place alongside the Southeast Asian kick-volleyball known as sepak takraw, the South Asian tag-and-catch game kabaddi, and a highly touted bodybuilding competition.

In the 1980s the Olympic Council of Asia replaced the Asian Games Federation in overseeing the Asian Games. The council has steadily broadened its purview by launching the Asian Winter Games, first held in Sapporo, Japan, in 1986 (with the sixth held in Chuangchun, China, in 2007); the Asian Indoor Games, begun in 2005 and including such non-Olympic sports as bowling, chess, aerobics, billiards, dance, and indoor soccer; and the Asian Beach Games, scheduled to begin in 2008 in Indonesia.

Asia-Pacific Economic Cooperation

Ya-Tai Jingji Hezuò Zuzhi
亚太经济合作组织

The Asia-Pacific Economic Cooperation (APEC) was established in 1989 to enhance economic growth and prosperity in the Asia-Pacific region. Its future, however, is in doubt.

APEC grew out of the same philosophy as that of the World Trade Organization (WTO): to promote the dismantling of trade barriers and to enhance the overall level of global trade. The underpinning economic philosophy is that of comparative advantage: each nation produces the goods it is most capable of and proficient at, and inefficient producers are not protected by tariffs. Hence waste is eliminated from production systems.

APEC also reflects the interests of its dominant members. The largest market for China and Japan is the United States, so a close association with America is important. China and Japan, in particular, also greatly depend on international trade for their wealth. China also needs Japanese investment and technological expertise, and Japan needs China’s low-cost labor to maintain the competitiveness of its manufacturing industries.

APEC is a result of the failure of the WTO to achieve global free trade. The WTO attempts to support and regulate trade among more than 150 countries, each with its own interest groups, nationalist pressures, and economic and political agendas. It is, therefore, difficult to achieve a consensus among them. The General Agreement on Tariffs and Trade (GATT)—formed in 1947 and dissolved in 1994, the forerunner of the WTO—struggled during...
its last nine years without gaining agreement (though of course it did make progress on a number of issues). The result of not securing agreement among so many disparate members led a number of countries to turn to regional economic groupings instead.

Open Regionalism

APEC differs from other RTAs in that it pursues open regionalism, whereas most others are "closed shops." This means that in most RTAs, members trade freely among each other but not with countries outside of the grouping. In APEC any member country can trade with a nonmember country but on the same principles that the members use with each other. In this case APEC is a core organization that can theoretically spread free trade to other countries.

Challenges for APEC

Unfortunately APEC has run into the same problems as did the WTO. Some industries in member countries are highly protected (e.g., agriculture in Japan), and it is difficult in political terms to make changes to this protection. In addition, APEC, like the WTO, contains both developing and developed economies, and it has been difficult to negotiate the relative speed of tariff reduction between the two groupings. Developing countries want more time to bring their tariff barriers down so that their economies are not overly damaged in the shift to free trade. Their concern is that if they move too quickly, developed countries will gain too much advantage in their markets. Conversely, developed countries continue to worry about trade imbalances, where low cost imports from developing countries may damage their industries, creating substantial trade deficits and boosting unemployment. The dramatic rise in Chinese exports to the United States is a case in point.

The result of such problems has led to APEC’s decline in importance over the years. Some experts say its only real purpose today is to provide a forum for heads of state to hold personal discussions and build working relationships. At these forums member countries also discuss matters not directly related to economics, such as how to deal with nonmember countries in the region, global warming, and terrorism.

In part the problem APEC faces is the sheer diversity found in the region. Unlike in the EU, in Asia there are very rich and very poor countries; Islamic and non-Islamic governments; countries dominated by rural populations and those that are primarily urban; countries with huge populations, such as China; and smaller city-states, such as Singapore. It is difficult for any economic agreement to take into account the interests of such a diverse group of nations.

The growth in free trade agreements (FTAs) around the world is an indicator of the failure of such organizations as APEC. Bilateral FTAs may often be difficult to negotiate, but it is far easier to integrate two economies than it is to integrate twenty-one economies, as in APEC, or more than a hundred, as the WTO has discovered. As of July 2007, 380 bilateral FTAs were in force around the world, with more in the planning stages.

The 2008 APEC conference in Lima, Peru, focused reducing the gap between trade in developed and developing countries, while leaders also addressed the current global financial crises.

Looking ahead

While the concept of APEC is a worthy one in terms of breaking down barriers to trade and investment (though not everyone supports free trade), attempting to negotiate multilateral agreements is a daunting task. In this sense APEC suffers from the same weaknesses as does the WTO, and both are in trouble today. In the long term, however, if the global economy is to grow fully, this difficult task is one that must be undertaken. China, like many countries in the region, has moved away from a focus on APEC and concentrated on engineering a range of bilateral and multilateral FTAs.

Further Reading

Atheism has had an enormous effect on the religious policy of the Chinese state ever since Western ideologies reached China around 1900. Since 1949 the officially atheistic Chinese Communist Party has sought to control rather than eliminate religion.

Because religion has been woven into the fabric of Chinese social life since ancient times, the rise to power of modern political forces, especially the avowedly atheistic Chinese Communist Party (CCP) in 1949, was likely to have a profound effect on the state and society. Would the Communist Party state pursue a policy of reckless suppression of religious life, or would it tolerate religion, at least temporarily? Except during the Cultural Revolution (1966–1976), the religious policy of the CCP has been guided by practical considerations rather than by its atheist ideology.

A Modern Concept of Atheism

Atheism here means a concept that rejects any form of religious belief. This definition does not include certain strands of Confucianism and Buddhism that are sometimes labeled as “atheist” on the grounds that they are not based on the concept of a personal deity. In fact, there is no reason to assume that they are incompatible with other forms of religion, and by and large in earlier times they did not interfere with sacrifices and other forms of worship. As far as religious policy was concerned, the imperial authorities tried hard to suppress “heterodox” teachings and practices that were regarded as a threat to the state; at the same time they sought to promote as well as control “orthodox” forms of worship.

Atheism as herein defined is a modern concept based on a strictly secular worldview. It entered China around 1900, along with a number of other ideologies imported from the West. Foremost among these were social Darwinism, nationalism, and socialism/communism. They were based on a specific notion of human progress and pursued a secular goal (a vigorous nation-state or a classless society) that served as a substitute for religious attitudes. Transmission of these ideas was intimately linked to the emergence of a modern Chinese intelligentsia. Young urban intellectuals who were attracted by the new ideological currents became hostile to any form of Chinese religion, including folk religion, Daoism, Buddhism, Islam, Christianity, and, although it is not a religion in the strict sense of the term, Confucianism, which came under fire for its association with the official cult of the state. Because these intellectuals formed the backbone of revolutionary movements and of the emerging political parties, atheism played an important role in the political transformation of China.

Atheism during the Republican Period

Chinese atheism was first and foremost directed against religion’s most “superstitious” form: folk, or popular,
religion, which also includes certain elements of Buddhism and Daoism. The republican revolution of 1911–1912 witnessed the first large-scale campaign against popular religion, in which many temples and shrines were destroyed. Although the provisional constitution of newly founded Republican China (1912–1949) guaranteed religious freedom, attempts to weaken the institutions associated with popular religion (temples, religious associations, etc.) continued until about 1915.

The May Fourth Movement (1915–1923), a pro-Western intellectual movement, gave rise to the next wave of antireligious activity. In addition to the general critique of religion (which was guided by a belief in modern science), two targets were singled out: Confucianism, regarded as the main cause of China’s conservatism and stagnation, and Christianity, by then regarded as an ally of Western imperialism.

The Chinese Nationalist Party (Guomindang [GMD]), which established a national government in 1925, to some extent succeeded the antireligious movements of the 1920s but was not clearly atheistic. The GMD did claim the supremacy of its ideology, the “Three Principles of the People,” over all forms of religion. However, some of its leading members (including Sun Yat-sen, Chiang Kai-shek, and their families) were Christians, and in the 1930s attempts were made to revive Confucian doctrines. This ambiguity notwithstanding, GMD governments at various levels campaigned against “superstition,” although with limited success.

### Atheism during the People’s Republic of China

The CCP took the Marxist view that religion is the opiate of the masses but that it will ultimately disappear in the transition to a classless society. However, the party dealt with religion within the framework of its united-front policy, a strategy designed to incorporate noncommunist social forces into the process of revolution and state building. Within this framework the party could form alliances with religious people despite its disapproval of religious doctrines.

The religious policy of the CCP was therefore guided by practical considerations rather than by a narrow ideological approach. Although the party was clearly atheistic, the state that it monopolized was not. This fact is reflected in constitutional law, which binds the state organs, although not the party. The constitution of 1954 granted citizens “freedom of religious belief” without being specific about what this guarantee exactly meant. The emphasis on belief rather than religious practice gave state and party the opportunity to suppress popular religion. Institutional religions were tolerated but brought under the supervision of the state. For that purpose a number of so-called patriotic religious associations were set up to represent the five officially recognized religions: Buddhism, Daoism, Islam, Catholicism, and Protestantism (the latter two being regarded as separate religions rather than as different branches of the same religion). The Bureau of Religious Affairs, founded in 1954, served as a link between the state and the patriotic religious associations but was also meant to guide and control the latter. In spite of the constitutional guarantees, all religious organizations were under heavy pressure from the authorities. This was especially true of those religions suspected of foreign domination, particularly the two Christian ones, even though all Western missionaries had been expelled from China during the Korean War (1950–1953).

During the Cultural Revolution all religions suffered from persecution and destruction. Leaders and activists were determined to eradicate religion, which was viewed as part of the “Four Olds” (old culture, old thinking, old habits, and old customs) that were to be destroyed. At the same time, constitutional law moved into the direction of state atheism. The constitution of 1975 declared that citizens enjoyed “freedom to believe in religion and freedom not to believe in religion and to propagate atheism.” In other words, atheist propaganda was constitutional, whereas religious propaganda was not.

In the course of the policy of opening up and reform initiated in 1978, the CCP has reassessed its religious policy. Although the party remains convinced that religion will eventually disappear as the result of the transition from socialism to communism and hence forbids its members to have any religious affiliation, it acknowledges that religion will continue to exist for some time. The constitution of 1982, therefore, not only confirms the right to freedom of religious belief but also establishes a framework for religious practice. The state protects “normal” religious activities, but it is unconstitutional to use religion to disrupt public order. Of course, this provision leaves
ample room for the authorities to decide which religious activities are “normal” and which are unlawful. The harsh treatment of Protestant “house churches” and the persecution of Falun Gong (a social movement with Daoist and Buddhist overtones) and its adherents, for example, must be viewed as attempts to maintain control over religious affairs and to suppress religious groups regarded as a threat to Communist rule.

A Delicate Balance

Ever since Western secular ideologies found their way to China around 1900, atheism has had an enormous effect on the religious policy of the Chinese state. However, although the political elites who ruled twentieth-century China were frequently influenced by atheism, they rarely tried to implement a thoroughly atheistic policy. They took measures to combat superstition in the form of popular religion but for the most part did not attempt to eliminate religion in general. Rather, they sought to control religious activities by officially recognizing a number of religious organizations. This is true of the most explicitly atheistic political party, the CCP. The Communists have tried to incorporate the major institutionalized religions into the state (the turmoil of the Cultural Revolution being the exception rather than the rule). In the 1980s and 1990s, not only the officially recognized religions but also popular religion experienced an astonishing revival, by and large tolerated by the authorities.

It is true that the Chinese state still has sufficient power to crack down on religious groups accused of threatening public order. If in the future it will tighten or loosen its grip on religion remains to be seen. That it will take steps to actively promote atheism—by force, if necessary—is far from likely.

The Australia China Friendship Society promotes better cultural understanding between people of the two countries. The society sponsors lectures, tours, and educational exchanges.

The Australia China Friendship Society (ACFS) was established in 1951 and 1952 in Melbourne and Sydney. During the 1950s and 1960s the society represented a coalition of societies whose objective was to develop friendship and peace with the people of China and the Chinese communities in Australia in an effort to foster better cultural understanding. The climax of such activities was the establishment of diplomatic relations between the two countries in 1972.

After 1972, when the society’s first national president, Geoffrey Stillwell, took office, the society promoted outbound tours to China, and during the 1990s the society promoted inbound tours from China.

Eight branches of the society are located throughout Australia. Membership in a branch is open to any person or corporation who agrees with the objectives of the society and pays the membership fee. As a voluntary, nonprofit, nonsectarian, and nonracially oriented organization, the society sponsors lectures, tours, film presentations, delegate meetings, educational exchanges, classes on society, language, and history, and exhibitions that tour in both Australia and China. The society’s staff is made up of volunteers from both countries.

National presidents succeeding Stillwell in chronological order have been Jack Lazarus (Victoria), Sidney Clare (New South Wales), Bruce Johnson (Tasmania), Tom Loy (Queensland), Jeff Emmel (South Australia), James Flower (New South Wales), and Keith Jenvey (Queensland). Loy was elected for a second term in 2008.

Australia-China Relations

China and Australia, whose Prime Minister, Kevin Rudd, is a fluent Mandarin speaker, enjoy a cooperative, mutually beneficial relationship, with trade and a healthy respect for differences in culture at the center. Australian tourism officials predict that by 2013, one million Chinese tourists a year will be visiting Australia—if the global financial climate improves.

China and Australia have an abiding relationship built on mutual trust and benefit. Even before President Richard Nixon’s historic visit to Beijing in 1972, Gough Whitlam, who became Australia’s prime minister that year, had visited Beijing. Since then, Australia has been a strong supporter of China’s quest to engage more fully with the rest of the world. In more recent times, Australia was a strong supporter of China’s accession to the World Trade Organization (WTO).

Spirit of Cooperation

Relations between China and Australia have never really been strained. In 1951, just two years after the founding of the People’s Republic of China (PRC), the Australia China Friendship Society (ACFS) was established in Melbourne and Sydney with the aim of promoting friendship and understanding between the peoples of Australia and the PRC. The ACFS is credited with contributing to the spirit of cooperation and the establishment of diplomatic relations between the two nations. Diplomatic relations were established between China and Australia in 1972. (The United States established diplomatic relations with China in 1979.)

Through the years a number of cities in China and Australia have established sister-city relationships, including Sydney/Guangzhou, Melbourne/Tianjin, Darwin/ Haikou, and Brisbane/Shenzhen. Such relationships have helped open the door to tourism.

Until the recent past, Chinese families did not take holidays to travel, even within China, so tourism is still new to many people. But as the economy grows and people enjoy more disposable income, Australia has become a popular destination for Chinese traveling abroad. Thanks to trade shows, entertainment troupes, art and cultural exchanges, and consumer goods imported from Australia—along with some Australian enterprises, like Aquaria 21, an indoor aquarium in Shanghai—the Chinese have come to know and appreciate all things Australian. Tourism officials in Australia predict an increasing flow of Chinese tourists in the coming years, with more than 1 million Chinese visitors expected by 2013, making China the largest tourism market for Australia. (All such estimates, of course, are based on reestablishing a strong global economy.)

Since the 1980s China and Australia have developed a variety of joint educational programs and cultural exchanges for students, teachers, researchers, and
professionals. Education is booming, with major Australian universities gaining a foothold in China. At the same time, loosened travel restrictions are allowing Chinese scholars more opportunities for study abroad.

Joint academic and training programs conducted in China take a variety of forms. Some programs involve partnerships between private enterprises; others involve cooperation between universities, research labs, and think tanks. Some programs take place entirely in China, some partly in China and partly in Australia. Some programs are designed so that one requirement or qualification is completed in China and then further study is completed in Australia. Some programs are in English while others are partly or wholly in Mandarin.

The two countries also cooperate in a number of important joint research projects. For example: In 2006 Chinese and Australian created a joint center for water research. The center has branches at the Chinese Academy of Sciences in Beijing and the University of Melbourne. A research agreement enables Chinese and Australians
to work together directly and to seek joint funding from sources outside China and Australia. The research focuses on such issues as groundwater management and irrigation techniques. In 2007 the Chinese Academy of Inspection and Quarantine and the Commonwealth Scientific and Industrial Research Organization, Australia’s national science agency, created a relationship agreement to conduct research in biosecurity and quarantine. These two organizations have had training and research agreements since the late 1970s.

Trading Partners

The spirit of cooperation between the two countries is strongest in trade and commerce. In 2005 China and Australia started negotiations on a free trade agreement that would benefit them both. Negotiations to hammer out the details continue; in the meantime, trade between the countries goes on.

Chinese imports from Australia include raw materials, manufactured goods and professional services. In the raw-material category, wool from Australian sheep has long been a important to China. To help drive its economic engine, China imports vast amounts of coal, iron ore, alumina, and liquefied natural gas (LNG) from Australia. An agreement finalized in 2002 calls for Australia to ship 3.3 million tons of LNG to China over a twenty-five year period, which began in 2006. The contract is worth $25 billion, Australian, ($16 billion, American) and represents Australia’s largest export contract, in terms of revenue, in its history. Supplying China has boosted the economies of Australia’s resource-rich states. The demand for resources in China is also creating a boom for Australia in related sectors that provide mining equipment, mining technology, and services to mining, such as software and training in areas like occupational health and safety. China also has major investments in mining and other energy projects in Australia.

Manufacturing imports have been growing steadily as well but are still small relative to the commodity sector. Nevertheless a demand for Australian goods of all kinds—consumer and industrial—has been growing in China. Some 4,260 Australian businesses export goods...
More than 3,000 Australian companies have bases in China to respond to this increased demand. Of particular demand from consumers are Australian products for children. Children’s natural-fiber clothing made by eeni meeni miini moh®, educational toys from GymbaROO®, and anything recorded or licensed by The Wiggles, a children’s musical group from Sydney, are extremely popular.

Importing services from Australia has become important to China, particularly financial services and professional services such as architecture, law, and engineering. Australian architecture firms—such as PTW, who designed the National Aquatics Center, known as the Water Cube, for the Beijing Olympics—are doing well as China invests in improving its infrastructure. Australian law firms are being called in to help China-based, Australian-owned firms conduct business in China. And as China meets the challenges of climate change, it is importing Australia assistance in environmental technology and design.

Although China exports some base metals and textile raw materials to Australia, it exports chiefly manufactured products: machinery, electronic products, audio-video equipment, chemicals and related products, footwear, headgear, umbrellas, artificial flowers, and a host of miscellaneous products, such as furniture, lamps, and toys.

China recently overtook Japan as Australia’s number one trading partner. In addition, the two countries have invested in each other as well. China has large investments in Australia’s resources and agricultural sectors, while Australia invests in Chinese manufacturing and some agribusiness and service businesses. Australia and
China undertake large joint ventures too—particularly in Liquefied Natural Gas (LNG).

**Strong Networks**

China’s favorable attitude toward Australia stems from a number of factors. The counties have gotten to know each other. There is been a long-standing link forged by migration—and more recently by trade—that connects the two countries. Chinese emigrants to Australia include business leaders, professionals, and workers. New Chinese emigrants generally have strong links to friends, family, and business and professional contacts back home.

On the cultural level, Australia has credibility in China with no historical political baggage. In recent years Australia has often supported China in international forums. Australia is strong economically and stable politically, with a highly skilled and multicultural workforce, including many ethnic Chinese. Chinese emigrants have influenced consumer tastes in Australia, which has helped to increased demand for exports and imports in both countries.

On the commercial level, Australia’s business culture suits the Chinese. The Chinese regard the Australians as open, direct, and honest. Australians doing business with China also tend to immerse themselves in Chinese culture and to learn Chinese ways. A study of Chinese workers found that an acceptance of cultural diversity by Australian managers was regarded as a key reason why Chinese workers liked working for Australian firms.

**Continued Relations**

It appears as though relations between China and Australia will continue to be mutually beneficial. Prime Minister Kevin Rudd of Australia is a fluent Mandarin speaker and keen scholar of Chinese history and culture. Leaders of the PRC have expressed interest in enhancing the two countries’ bilateral trade, cultural, and strategic ties. The Australian-China relationship is pivotal to both the nations and their peoples.

Some 118 million vehicles, over 60 percent privately owned, were traveling China’s roads by 2007, although sales sagged in 2008. Despite the decline, in January 2009 China seemed on its way to becoming the largest auto market in the world. The government hopes that by 2013 one in ten cars built in China will run on alternative energy.

The Western image of China as a nation of bicyclists is anachronistic; cars are fast replacing bicycles as China’s standard mode of transportation. The economic reforms of the 1980s led to twenty years of rising income, creating a consumer society where it is now easier for people and businesses to buy many different products, including passenger cars, pickup trucks, and SUVs. Based on statistics for the month of January 2009, with China car sales (735,000) surpassing for the first time those of the United States (656,976), China seems to be on the way to becoming the world’s No. 1 vehicle market (Kurtenbach 2009); China is already the No. 3 or No. 4 manufacturer—depending on the period measured—behind the United States, Japan, and Germany. Sales of both imported and domestic-made models are forecast to grow steadily in the coming years, as long as the overall economy remains strong. China’s automobile industry has developed from a cottage industry producing outdated Russian designs to a major world player in just one generation. The growth of the auto industry is one more indication of China’s economic power.

Early Days

The first car in China arrived in 1902, thanks to Yuan Shikai (1859–1916), a high military official of the Qing dynasty and, later, Sun Yat-sen’s (1866–1925) successor as president of the Chinese Republic. Yuan imported a car made by the Hong Kong plant of the American firm of Charles and Frank Duryea. He bought the car to win favor with Empress Dowager Cixi (1835–1908). By 1913 Henry Ford was selling his famous Model T in Shanghai.

China traces its auto industry to production dates from 1931. That year Tang Zhongming (1879–1980), an engineer and inventor, built an internal-combustion engine powered by charcoal, which he mounted into a car. This machine was meant to be used as military vehicle by Tang’s patron, Yang Hucheng (1893–1949), a Guomindang general during the Chinese Civil War.

The first modern automaker, First Automobile Works—now known as First Automotive Group Corporation, or FAW—began producing cars and trucks, using Soviet technology, in 1953 in Changchun, Jilin Province. FAW remains one of the “Big Five” automakers in China.

During the 1950s and 1960s, with the help of the Soviet Union, Chinese factories produced light- and heavy-duty trucks for military and civilian use. Several more automobile enterprises opened, including The Second Automobile Works—now known as Dongfeng Motor Corporation—founded in Hubei Province in 1968. The construction of this plant was part of Mao Zedong’s (1893–1976) Third Front strategy, a massive project of industrial development intended to provide homeland...
security. Similar plants were set up in other provinces and major cities throughout China, often with one venture for cars and another for trucks.

**Joint Ventures**

During the Cultural Revolution (1966–1976), all of China’s industries were in turmoil, and production declined. But transport was understood to be crucial and foreign exchange constraints limited the import of vehicles; building a modern automotive industry became a goal of the post-1978 leadership. As part of the reforms of late 1970s and early 1980s, China’s leaders realized that a thriving automobile industry could contribute to economic development and attract foreign investment. But Chinese enterprises lacked the technology and the capacity to design and manufacture cars. So China turned to foreigners to acquire the needed technologies, usually by forming joint ventures. Because autos were considered a strategic industry in China, government policy limited foreign firms to a 49-percent stake in vehicle assembly plants. Thus, despite foreign firms’ attraction to China’s huge, untapped car market, joint ventures were the only means of entry. To date only one firm (Honda) has been able to obtain an exception using a promise of exports.

Since the 1980s, joint ventures of Chinese and foreign-owned companies have powered China’s auto industry. The Chinese government and Chinese businesses generally prefer the joint venture to other business structures when dealing with foreign companies. Joint ventures do, however, benefit the foreign investor by providing a local partner, typically a state-owned enterprise, thereby allowing the foreign investor favorable access to China’s huge markets and labor force. The Chinese benefit from the manufacturing, technology, and marketing experience of the foreign partner. Four of China’s Big Five automakers operate through joint ventures.

FAW had been producing medium-sized trucks since 1956 and its own car brand, the Hongqi, since 1958, when it formed a joint venture with Volkswagen in 1991 to focus strictly on cars. Since then, FAW has formed many joint ventures with businesses from around the world, including the United States, Russia, and Japan, to produce cars and parts.

In 1984 Volkswagen and the Shanghai Automotive Industry Corporation (SAIC) formed Shanghai Volkswagen Automotive Company, Ltd., (SVW), a 50-50 joint venture fixed for forty-five years. SVW is the largest foreign-invested enterprise in China in terms of sales. The company produces more than 450,000 cars a year and is headquartered in Anting International Auto City, in the Jiading district of Shanghai.

Dongfeng Motor Corporation also has joined in a number of joint ventures since the 1980s, including agreements with Peugeot/Citroen, Honda, Nissan, Kia, and Hyundai. It manufactures and assembles cars, trucks, buses, and parts under its own name and with its foreign partners. Although the corporation’s stocks are publicly traded, the Chinese government maintains 70 percent control of the company.

Chang’an Automobile (Group) Company, Ltd., (also called Chang’an Motors, Chang’an Auto, and Chana Auto) is the fourth-largest auto producer in China. It is headquartered in Chongqing, a provincial-level municipality in western China. Chang’an was founded in 1862 in Shanghai and developed the first industrial group in modern China, manufacturing a variety of products, including guns. In 1957 in began producing Jeeps. The company has joint ventures to build cars and engines with Suzuki, Ford, and Mazda.

Chery, the fifth-largest automaker in China, is owned by the local government of Wuhu, Anhui Province. Chery is the largest independent auto manufacture in China. Although it has not engaged in any joint ventures with foreign or domestic enterprises, it has formed strategic partnerships with companies in the United States, Austria, and Iran, and has plants in Iran, Russia, and Egypt.

Forming joint ventures for domestic manufacturing has been an effective business strategy for China’s automakers. Throughout the world the auto industry’s long-term tendency is to build where vehicles are sold. This way automakers need not worry so much about fluctuations in foreign exchange rates and the need to adapt products to match the unique nature of foreign markets.

China’s Big Five automakers take part in over a dozen loosely-integrated joint ventures. There are in addition about forty other smaller companies, operating under the protection of provincial governments. This contrasts with twelve firms in the United States, the world’s largest market. In the past, provincial governments were able to
impede outside firms from selling in the local market; such local protectionism has now receded. The overall market thus remains highly fragmented, and with the exception of a few joint ventures (SAIC-VW, SAIC-Buick, and the main ventures of Honda and Toyota) most firms operate at too low a volume to realize economies of scale yet face pressure to meet modern emissions and safety standards. There will inevitably be a shake out over the next few years.

**Makes and Models**

China’s Big Five automakers, along with about forty other smaller companies, produce the full range of commercial and passenger vehicles and parts and components. The following focuses on several Big Five specialties.

FAW produces commercial trucks and buses, coaches, passenger cars, SUVs, pickups, and parts under license from Toyota, Volkswagen, Audi, and Mazda. Its best known make, however, is its own Hongqi, a luxury sedan and limousine favored by the rich and by government leaders since the 1950s. In 2006 FAW launched the Besturn series of high-end performance luxury cars.

SAIC makes licensed versions of Volkswagen and General Motors vehicles. GM is the top-selling brand in China. In addition, SAIC makes the Roewe 750, a highly revised version of the Rover 75; MGs, including the Austin, Morris, and Sterling; and the Soyat, a Chinese brand.

Dongfeng produces commercial vehicles, including trucks and buses, and passenger vehicles, including sedans and SUVs, under licensing arrangements with its joint-venture partners.

Chang’an Motors builds licensed versions of Suzuki, Ford, and Mazda commercial trucks and passenger vehicles. In 2005 the company introduced its own car brand, the Chang’an CM8. For the 2008 Olympic Games in Beijing the company supplied a number of hybrid-drive cars as taxis for athletes and spectators.

Chery makes large and mid-size sedans, city cars, and panel vans, with such names as Cowin, Eastar, Tiggo, and Karry.

**Parts and Accessories**

An important part of the auto industry in China is the auto parts sector, which in the United States, Japan, and Europe accounts for roughly three times the employment of
the automotive assembly sector. By the end of 2007, there were 7,579 makers of auto parts and fittings in China, 72.3 percent of the entire auto industry in terms of the number of manufacturers. Revenue from the auto parts sector accounted for about 35 percent of the entire industry’s revenue and about 41 percent of the profit. Unlike the auto assembly plants, most parts plants were private companies (5,137), the rest being either foreign owned (1,120) or state owned (1,322).

Certain subsectors of the auto parts sector—particularly engines, chassis, tires, and auto electronics—have been expanding rapidly in recent years. The auto parts sector has been able to meet about 60 percent of China’s demand for parts and accessories, although competition from foreign auto parts makers has been increasing. To meet the competition, the government has been developing policies to help the domestic parts makers to become more competitive through acquisitions and mergers or by going public.

**Steady Growth**

China’s auto industry has grown dramatically since the 1990s. In 1990 only 42,000 cars were produced in China, compared to some 5 million in the United States. By 2000 production in China had jumped to 2 million units. Production grew to 7.2 million vehicles in 2006 and more than 8.8 million in 2007. (The United States produced about 10 million vehicles that year.) Industry analysts predict that by 2020 China’s auto industry will be the largest in the world.

Sales for Chinese-made cars have been brisk in recent years. China itself is the main market. In 2007 the top ten passenger-vehicle manufacturers in China sold 3,062,561 cars, about 65 percent of the total national sales.

In 2007 Shanghai GM, a joint venture between General Motors and SAIC, sold 500,308 vehicles, leading car sales in the Chinese market for the third consecutive year. Shanghai GM is the first passenger-car company in China to sell more than 500,000 vehicles a year. In 2007 Shanghai GM sold 160,500 Chevrolet vehicles, up 56.4 percent from 2006; 332,000 Buick vehicles, an increase of 27,800 units from 2006; 7,040 Cadillac vehicles; and 618 Saab vehicles.

FAW-Volkswagen, a joint venture of FAW and Volkswagen Group of Germany, sold 459,359 vehicles in 2007. The Jetta accounted for 43.49 percent of the total volume.

Shanghai-Volkswagen, a joint venture between SAIC
and Volkswagen Group, sold 436,343 vehicles in 2007. Just four models—Passat, Santana, Santana 3000, and Polo—represented 91 percent of its total sales.

Chery in 2007 sold 381,000 vehicles; 119,800 were exported.

The fastest growing automaker in China in 2007 was Chang’an Ford Mazda, a joint venture between Chang’an Motors, Chang’an Ford, Ford Motor Company, and Mazda. The company was formed in 2005. In 2007 it sold 217,100 vehicles, a 60-percent increase over 2006 sales. Also in 2007 a spin-off company, Chang’an Ford Mazda Engines, began producing the Mazda Z engine for use by Chang’an Ford.

The top ten automakers, in terms of sales, in 2007 were FAW-VW, Shanghai-GM, Shanghai-VW, Chery, FAW-Toyota, Dongfeng-Nissan, Guangzhou-Honda, Chang’an-Ford-Mazda, Dongfeng-Peugeot-Citro, and Beijing-Honda.

Meanwhile, as noted above, the integration of the national market is intensifying competition, and with a dozen-plus firms investing in new capacity, prices have been forced down, despite this growth in demand. Rising sales do not always mean rising profits. As early as the second quarter of 2007, China’s automakers began to see profits dip. The increased cost of materials, most notably steel and energy (mainly coal), had begun to cut

In the last two decades China has built many super highways. While China produces its own makes of cars, joint ventures with international car makers and foreign cars offer potential car buyers a choice. PHOTO BY TOM CHRISTENSEN, CAPTION BY JOAN LEBOLD COHEN.
into earnings. And sales flattened in 2008 in China, as was the case with car sales around the world.

Export Market

While most of the cars sold by Chinese automakers remain in China, the automakers had been gradually penetrating foreign markets until the financial crisis of 2008. Rising production and demand generated a record year for exporters in 2007. Exports rose 79 percent from the previous year. Automakers shipped 612,700 vehicles and chassis overseas. Trucks accounted for 40 percent of exports; passenger cars, 31 percent; and buses and chassis, the rest. Automakers and parts makers sold their products in 220 countries and regions. The value of exports more than doubled from 2006 levels to reach $7.31 billion.

But by the third quarter of 2008, the export bubble had begun to burst. Exports were down 20 percent from the previous year. China’s major export markets—Russia, Vietnam, South America, and Central America—were experiencing their own financial problems. In addition, Russian and other countries raised their trade thresholds, which obstructed Chinese auto exports.

Quality issues have also affected exports. Chinese automakers had been trying for years to crack the U.S. market as they have the European market. By the end of 2008, Chinese cars still had not met the emissions and safety standards demands of the United States.

Domestic Market

As of 2007 China was the world’s second largest car market, following the United States. In 2007 Chinese drivers bought 8.8 million cars, minivans, and SUVs, and 3 million commercial vehicles, up from just 1.6 million vehicles sold in 1997. China is the largest market in the world for Volkswagens. In 2007 some 118 million vehicles were traveling China’s roads, 61.2 percent privately owned. Owing to improved technology and sales mechanisms, China-made cars are good value for the money.

The fastest growing segment of the Chinese car market is the first-time buyer, estimated to be 80 percent of China’s car buyers. Fewer than 50 of every 1,000 Chinese own cars. In the United States, 750 Americans of 1,000 own cars. The worldwide average is 120 of 1,000. In the so-called mature markets like the United States, Europe, and Japan, first-time buyers account for less than 15 percent of the market.

Although most of the sales of Chinese vehicles, including cars, are sold to the Chinese people, many buyers still prefer imported cars. Jaguars, Landrovers Escalades, Humvees, Range Rovers, and other high-end Mercedes SUVs are extremely popular with China’s newly rich. Sales of BMWs rose 42 percent in 2007.

Some months in 2008 saw declines in sales; some months saw gains in sales. But, overall, sales of both domestic and foreign cars remained flat in 2008. Chinese car owners were more concerned with the cost of gasoline, which was expected to continue to rise, than with the cost of new cars. China’s newly rich first-time buyers, however, showed little concern for costs in 2008 and continued to buy Chinese cars and gasoline. Nevertheless, because of the global economy and the ripple effect, China’s auto industry was not immune to the financial turmoil of 2008. By the end of the year, there was much talk among automakers and policymakers about rebuilding consumer confidence, finding ways to fight foreign competition, and planning China’s first large-scale restructuring of the industry. But based on figures for the month of January 2009, China overtook the United States in number of car sales (735,000 and 656,976 respectively). If China’s pace continues, and the U.S. figures continue to plunge, China will become the leading auto market in the world. According to Mike DiGiovanni, General Motors’ executive director of global market and industry analysis, China’s expected auto sales could reach 10.7 million units in 2009, while he projects a figure of 9.8 million for the United States (Kurtenbach 2009).

National Impact

China’s auto industry is but one industry driving the economy, but it has had a large impact—both negative and positive—on the nation and the people. It is expected to affect the economy, government policy, and social institutions for years to come.

Before 1980, when there were relatively few passenger cars in China, urban air pollution was much lower than it is now. Also, in part because there were fewer cars, the country did not consume the huge quantities of oil—domestic
or imported—that the United States and other countries used. Since 1980, motor vehicles have become the leading source of urban air pollution, and China’s demand for oil has skyrocketed. By 1993 China became a net importer of oil for the first time. By 2004 China was the fourth-largest importer and by 2005 the second-largest consumer of oil in the world. To address pollution, China has now eliminated the use of lead gasoline, and requires catalytic converters and other standards that reduce emissions. Many old vehicles remain in use, and the regulation of trucks lags behind that of passenger cars.

Upgrading the auto industry and providing more roads for all the new cars are two key component of the government’s eleventh five-year plan (2005–2010).

Upgrading, according to the plan, has been gradual and has focused on strengthening the industry through steady, sustainable growth, innovation, and increased vocational training to provide workers for the auto industry (and other industries as well). The production of cleaner, more fuel-efficient cars is byproduct of the plan with far-reaching effects.

The plan called for investing $700 billion in the highway infrastructure. The goal is to build 2.3–2.5 million kilometers (about 1.2 million miles) of new road, including 55,000 kilometers (about 34,000 miles) of expressway. Expressways are being built to connect all cities with populations of 200,000 or more.

The complex interplay of China’s auto industry with a growing and affluent middle class, shifting foreign and domestic markets, foreign competition, environmental concerns, and government policy is bound to have a profound effect on China’s future prospects.

Future Prospects

The future of China’s auto industry—and the auto industry throughout the world—remained uncertain at the end of 2008, but statistics for January 2009 proved hopeful. Full results of the eleventh five-year plan had yet to be realized. Many analysts believe that China’s auto parts sector will continue to do well and show the greatest gains in employment, exports, and profits.

One positive note is China’s interest in electric motor scooters and cars. The country has invested heavily in the technology to build and keep running hybrid motor scooters, cars, and buses. Electric-car charging stations have been built in Shanghai, Beijing, Tianjin, and other large cities as part of a pilot project. The hope is that by 2013, one in ten cars built in China will run on alternative emery.

The government has designated the automobile industry as one of the pillars of its economic growth and development. Much planning and work will be done to keep China’s auto industry one of the most dynamic and prosperous in the world.

Autonomous Areas ▶
A fundamental aspect of China’s policy regarding ethnic diversity is the constitutional establishment of autonomous areas, where the majority of inhabitants are traditionally ethnic minorities. Autonomous areas, occupying 64 percent of China’s total territory, exist at several levels, the largest being the province-level autonomous regions, followed by autonomous prefectures, autonomous counties and banners, and, since 1993, autonomous or ethnic townships.

China has many policies and practices directed at ethnic minorities. Some have aimed to improve the situations of such groups; others have targeted relations between minority groups and the Han majority. Still others have aimed to pacify such groups. And yet others have aimed to integrate and assimilate such groups. One such policy, emulating the Soviet model, involved the establishment of a set of autonomous areas—commonly referred to specifically as autonomous regions, prefectures, or countries—even before establishment of the People’s Republic of China in 1949.

Autonomous areas come in three sizes, the largest being provincial-size autonomous regions (zizhiqu, 自治区 of which there are five). There are also 30 autonomous prefectures (zizhizhou 自治州) and 120 autonomous counties (zizhixian 自治县) or autonomous banners (autonomous areas the size of counties in Inner Mongolia, zizhiqi 自治旗). Because some areas are too small, or too much mixing of ethnic groups prevents the formation of an autonomous county, in 1993 autonomous or ethnic townships (zizhixiang 自治乡) were established to supplement the other three types of autonomous areas; by 2003 there were 1,173 of these townships.

Autonomous areas occupy 64 percent of China’s total territory. Of the fifty-five recognized ethnic minorities,

forty-four have autonomous areas devoted to them, accounting for 71 percent of ethnic minorities.

The first autonomous region was the Inner Mongolia Autonomous Region, established in 1947, even before the founding of the People’s Republic. The last autonomous region established was the Tibet Autonomous Region, not founded until 1965. Some scholars regard the late date as evidence that the central government was aware that this region would not be easily settled.

Some of China’s best-known ethnic tourism sites are autonomous areas, such as the Xishuangbanna Dai Autonomous Prefecture and the Dali Bai Autonomous Prefecture, both in Yunnan, and the Yanbian Korean Autonomous Prefecture on the border with North Korea. Most autonomous areas lie in the border areas of China, where the majority of inhabitants were traditionally ethnic minorities and where relations with other nations are sometimes delicate and unsettled.

All autonomous areas share the same guiding and foundational principles, which recognize these areas as the traditional home area of a particular ethnic minority living in “compact communities,” after which the autonomous area derives its name. (Areas can be named after more than one ethnic group.) Minority representation

in government is encouraged, although usually not at the highest levels.

The term translated as “autonomy” is zizhi (self-governing), but the autonomous areas have no actual autonomy, and the inseparability of the autonomous areas from the rest of the Chinese nation was specified immediately with the introduction of the idea of regional autonomy in the First Constitution (September 1954): “Regional autonomy applies in areas where a minority nationality lives in a compact community. All the national autonomous areas are inseparable parts of the People’s Republic of China.” By law governments of these areas are required to “safeguard the unification of the country.” This policy was reaffirmed in 2001 in the Law of the People’s Republic of China on Regional Ethnic Autonomy. Article 2 states, “Regional autonomy shall be practiced in areas where minority nationalities live in concentrated communities. National autonomous areas shall be classified into autonomous regions, autonomous prefectures and autonomous counties. All national autonomous areas are integral parts of the People’s Republic of China.” Further, as a result of many migrations since 1949, it is no longer necessarily the case that the ethnic group after which an autonomous area is named is in fact the majority resident of that area now. Most areas now have a majority Han population.

One of the most influential and popular modern Chinese writers, Ba Jin critiqued the harsh realities of feudal China, which he saw as oppressing and destroying the individual. Being a life-long anarchist, he advocated change through revolutionary means.

Considered one of the most influential Chinese writers of the last century, Ba Jin was born in Chengdu, Sichuan Province. His birth name was Li Yaotang. Ba Jin is a pseudonym he adopted when he began to write. It is thought that his pen name comes from two Russian anarchist writers, Mikhail Bakunin and Pyotr Kropotkin, who greatly influenced him in his early years. Another explanation suggests that the name is the initials of a friend who committed suicide.

Ba Jin was born into a large and influential family of court officials. His early education was spent studying English, at which time he became a voracious reader and eventually found great affinity with anarchist writers such as Bakunin, Kropotkin, and Emma Goldman. At the age of sixteen, he joined a group of anarchists. Perhaps the appeal for radical politics came from his hatred of his own family life, which he found to be tradition-bound and oppressive. In 1923 he entered Dongnan University in Nanjing, where he further pursued his anarchist aspirations, organizing strikes and writing pamphlets.

After graduating in 1927, he left for Paris, where he began to pursue an active literary career. During his year in France, he wrote his first novel, *Destruction*, and translated many anarchist works into Chinese. He returned to China in 1928, took up residence in Shanghai, and began to write in earnest. In 1933 he published *Family*, a novel in which he showed the cruelties of a repressive family bound to feudal conventions. This was the first entry of a trilogy known as the Torrents Trilogy. The other two novels were *Spring* (1938) and *Autumn* (1940). Other notable novels by Ba Jin from the 1930s include the Love Trilogy: *Fog* (1931), *Rain* (1933), and *Lightning* (1935); *Autumn in Spring* (1932); *A Dream of the Sea* (1932); and *Miners* (1933). During the 1930s, he continuously wrote essays, which were published in various important literary journals, and undertook translations. The main themes of his writing were the cruelty of an effete traditional society and the promise of modernity. Thus Ba Jin’s writings became an essential part of what would become contemporary China.

During World War II, Ba Jin worked actively against the Japanese invaders, and when the Communists took control after the war, he welcomed them enthusiastically. However, this zeal was short lived when he and his activities were seen as suspect. During the Cultural Revolution, Ba Jin was labeled a subversive, and his writings and ideas were suppressed. These were difficult and painful times for him. In 1972 he lost his wife to illness because medical treatment was denied them both. It was only in 1977 that he was rehabilitated and his writing was again allowed to be printed.

In 1981 he was elected chairman of the Chinese Writers Association, during which time he actively advocated freedom for writers and even proposed a museum dedicated to the Cultural Revolution to ensure that such an event would never happen again. His suffering during this time is
Ba Jin and The Family

Ba’s trilogy focuses on the ills of traditional Chinese society and the old family system. It is the longest and most ambitious piece of modern Chinese fiction before World War II. Ba Jin admitted that he drew upon family life he knew during his adolescent years in Chengdu for his novel.

The Family is a true story, in that its characters represent people I loved or loathed. Some of the events I personally witnessed or experienced. As I said previously: “I don’t write novels in order to be an author. It is my past that force me to take up my pen.” Writing The Family was like opening memory’s grave. Even as a child I frequently witnessed the ruination of the lives of loveable young people who were driven to a tragic end. When writing this novel, I suffered with them and, like them, struggled in the grip of a demon’s talons. It is replete with my deep love, my intense hate.

chronicled in his five-volume work titled Random Thoughts. In 1990 he was given the Fukuoka Asian Culture Prize. Ba Jin died in Shanghai in 2005 at the age 100 or 101.

For thousands of years bamboo has been an important practical and cultural product in China. People have used it for food, crafts, and weaponry, and to make bridges, residences, and household items.

China has used bamboo for thousands of years. Ten thousand years ago hominids (erect bipedal primate mammals comprising recent humans together with extinct ancestral and related forms) living along the Yangzi (Chang) River used bamboo. During the Shang dynasty (1766–1045 BCE) people used bamboo to make arrowheads. During the Spring and Autumn period (770–476 BCE) people carved words on bamboo strips and used them to send messages. During the Qin dynasty (221–206 BCE) people made pens of bamboo, and during the Jurchen Jin dynasty (265–316 CE) people made paper—one of the four great inventions of ancient China—from bamboo. During the Song dynasty (960–1279) bamboo was used as a weapon.

Chinese people have long used bamboo in daily life. Su Shi, a scholar during the Song dynasty, wrote: “Bamboo shoot for food, bamboo tile for house making, bamboo hat for rain sheltering, bamboo wood for fuel, bamboo skin for clothing, bamboo paper for writing and bamboo shoes for foot wearing, that is the life—we can not do without bamboo” (Zhaohua 2001).

In general bamboo has had four uses during China’s long history: as a versatile and durable natural resource of value in all aspects of daily life, as decoration, in weaponry, and as a cultural symbol.
Daily Life

As early as the Spring and Autumn period, the production of bamboo occupied an important position in agriculture, fishing, industry, and domestic life. The Han dynasty (206 BCE – 220 CE) made about 60 kinds of everyday items out of bamboo; the Jin dynasty made about 100; the Tang (618–907 CE) and Song dynasties, more than 200; and the Qing dynasty (1644–1912), about 250 items. The most familiar were rulers, curtains, fans, rafts, and cases, which are still common today.

Bamboo also was used in the Du Jiangyuan hydraulic engineering works two thousand years ago, and people in Sichuan Province dug a salt well 160 meters deep using bamboo rope during the Han dynasty.

Bamboo was a dependable building material, especially in southern China. In Yunnan Province several minorities, such as the Dai and Zhuang, used bamboo pavilions as their main residences, and before the popularization of steel and concrete, bridges were built of bamboo.

Chinese also have long valued bamboo for the taste and nutritional value of its shoots. “There is no banquet without bamboo” was an often-heard saying during the Tang dynasty. In 1006 BCE the Emperor Zhou Cheng entertained his subordinates with a “bamboo shoot banquet.”

Decoration

Basket weaving was at the core of ancient bamboo culture. Basketry began during the early Neolithic period (8000–5500 BCE), and the Warring States period was the turning point of the craft as it gradually developed into a decorative art. During the Tang and Song dynasties exquisite bamboo lanterns and other woven products were used in everyday life. In the Ming (1368–1644) and Qing (1644–1912) dynasties, with the growing number of bamboo basketry artists, the types of household items bearing intricate bamboo decoration only increased.

Bamboo carving is another traditional craft. A Han dynasty bamboo spoon with a dragon pattern, found in the Mawangdui Tomb in the city of Changsha, was the earliest practical example of bamboo carving. During the Ming dynasty bamboo carving developed into an art.

Weaponry

One of the earliest uses of bamboo was in crafting arrows and lances. An ancient legend about "Hou Yi shooting the sun" featured a bamboo bow and arrow. During the Han dynasty, bamboo pieces carved with characters and patterns to represent military leadership were used as a commanders’ tallies. (Afu, the Chinese word for tally, was a form of credential or authority, or could also function as a passport). When the general was leading an army to fight, the king would give the general one half of the bamboo symbol and keep the other half. If he needed to send orders to the general, the king would let his representative take his half of the bamboo symbol and show it to the general to verify the authenticity of the orders. Bamboo played an important role in the military as bamboo guns were produced during the Southern Song dynasty.
(1127–1279). People filled the long culm (stem) with the predecessor of modern gunpowder. During the end of Han dynasty (208–280 BCE), rattan armor was the most important protecting method in Chinese southwestern national minorities.

**Culture**

In ancient Chinese culture bamboo was the symbol of good fortune and longevity, valued for its tenacious properties and its transcendent beauty; an appreciation for bamboo was considered the mark of a gentleman. Indeed, many bamboo qualities were said to symbolize those of noble human beings—its strength and solidity, for instance, representing a person’s faithfulness and firmness; its hollowness a symbol of a modest personality. Thus, bamboo became a common subject of painting and poetry. The earliest collection of Chinese poetry, *Shijing* (*Book of Songs*) (1046–771 BCE), included five poems about bamboo. Traditional Chinese alphabetical characters also reflected the importance of bamboo in the culture. Until the Qing dynasty 960 characters bore the bamboo radical. (Word radicals are the building blocks of most written Chinese words, or pictograms. Each radical conveys a certain message, either of an object or an abstract idea, which, when combined, link the core ideas to the more complex meaning of the word.)

Inspired by their traditional use of bamboo Chinese people summarized many valuable experiences and wrote related books, such as *Chinese Bestiary*, which was published in the fourth century BCE and described the distribution, characteristics, and economic values of ancient bamboo resources, and the first bamboo monograph, called “bamboo spectrum,” which in the sixth century CE described seventy bamboo species. Most of the descriptions were in accordance with modern research.

Bamboo indeed is the essence of Chinese history. As the British scholar Joseph Lee said, “East Asian civilization is bamboo civilization” (Zehui 2002).

Bank of China
Zhōngguó Yíngháng 中国银行

The Bank of China, one of the pillars of China’s financial infrastructure, holds a unique place as the most recognizable and international institution in the national banking system. The bank has survived numerous political transitions and economic systems and is poised to become a powerful player in the global financial scene.

Over the past century, the Bank of China (BOC) has had a hand in virtually all of China’s major financial efforts. The Bank of China had roots in a bank established by the Qing government in 1905 to serve as a central authority for the Imperial Board of Revenue. It issued notes in 1908 but did not have a powerful national presence until it was formally founded, with Sun Yat-sen’s approval, as part of the establishment of the Republic of China in 1912. The BOC served as China’s primary fiscal and financial authority until 1949 and the founding of the People’s Republic of China. During the volatile period from 1912 to 1949, the bank served as one of the few stable sectors in the country. Through prudent expansion into increasingly stable areas and with prompt response to political changes, it managed to maintain its position of power and influence throughout. In 1929 the bank opened its first international branch, in London.

After the revolution of 1949, BOC was relegated to a secondary role from the newly established People’s Bank of China (PBC). The PBC controlled domestic financial and fiscal policy and was tightly controlled by the central politburo. BOC, fully nationalized, was used primarily as an international exchange bank and served mostly in this role. This thirty-year period was typified by extreme economic isolation, with all foreign banks having been required to exit the country. Representatives of the Bank of China were frequently the representatives in international trade discussion.

During and after the formal opening of China in 1979 and 1980, BOC changed from being just the international financial face of China to being the largest commercial bank. The bank took several notable steps to provide a greater range of financial services, issuing international bonds in 1984 in Japan. Japan provided BOC with one of its most fruitful initial international presences, as it was able to participate in Japan’s economic boom during the late 1980s and early 1990s. In the 1990s the bank expanded its international role, using its position as the primary international bank of China to attract internationally experienced professionals to its management team. Focusing on modernizing its operations, it became the note-issuing bank of Hong Kong and Macao, and established several subsidiaries, including BOC Hong Kong, BOC International, BOC Insurance, and other lesser financial entities.

In 2003 the Bank of China became one of the pilot banks for a new project to engage in reforms to give banks more leverage to compete in international markets. On 26 August 2004, Bank of China, Ltd., was formally incorporated as a state-controlled commercial bank, a unique institution in the financial world. As a commercial bank,
it accepts deposits and makes loans to individuals and businesses.

Bank of China has more than 10,000 branches in China and more than 600 branches in 27 countries, including Canada (Toronto and Vancouver) and the United States (New York and Los Angeles). Around the world, it employs more than 200,000 people. It has assets estimated at 3 trillion yuan (about $385 billion) and has been included in the Fortune Global 500 for 17 consecutive years.

Further Reading

Foreign banks and two traditional types of Chinese banking institutions dominated China’s financial market during the Qing dynasty. Modern banks combining Western techniques with China’s indigenous practices would emerge to play an important role in Chinese economy by the mid-1930s. But Japanese invasion, subsequent civil war, and the establishment of the Peoples Republic of China put a halt to this development.

During the entire nineteenth century, China’s financial market was dominated by foreign banks and two traditional Chinese financial institutions: piaohao 票号 and qianzhuang 钱庄. The piaohao, started in the early nineteenth century, rapidly developed into the most powerful force in the contemporary Chinese financial market. Piaohao focused on interprovincial remittances and conducted government services; high officials and big merchants were their main customers. By the end of the nineteenth century, thirty-two piaohao, with 475 branches, were in business covering all of China’s eighteen provinces, plus Manchuria, Mongolia, Xinjiang, and other frontier areas.

Independent of the nationwide network of piaohao were a large number of small native banks called qianzhuang. From the beginning, qianzhuang had their own field of business complementary to, but distinct from that of, the piaohao. Most qianzhuang were local and functioned as commercial banks by conducting local money exchange, issuing cash notes, exchanging bills and notes, and accepting discounts for the local business community. Until the middle of the nineteenth century, qianzhuang and piaohao served the Chinese economy and society well.

The growth of China’s import and export business in the nineteenth century attracted Western banks into China’s financial market. A British-Indian bank introduced modern banking into China in 1845; other European, American, and Japanese banks followed. By the end of the nineteenth century, there were nine foreign banks with forty-five branches in China’s treaty ports, all of which, by virtue of extraterritoriality treaties imposed on China, operated outside the jurisdiction of the Chinese government. Not only did these banks completely control China’s international-remittance and foreign-trade financing, they also issued their own banknotes, accepted deposits from Chinese citizens, and extended loans to traditional Chinese financial institutions.

By the end of the nineteenth century, foreign banks dominated the financing of China’s import and export trade, while piaohao monopolized the domestic remittance business and qianzhuang controlled credit markets for domestic trade throughout China. Complementing and cooperating with each other these three institutions monopolized the Chinese financial market so tightly that there seemed to be little room for modern Chinese banks.
Emergence of Modern Chinese Banks

The dominance of foreign banks, qianzhuang, and piaohao in the Chinese financial market was finally broken when China’s first modern bank, the Imperial Bank of China, opened for business in Shanghai in 1897.

China’s New Financial Demands

The birth of the modern Chinese bank was first the result of China’s new financial demands. Decades of commercial contacts with the outside world and the bitter experiences of military defeats at the hands of Western industrial nations convinced increasing numbers of Chinese of the superiority of machine production over the century-old handicraft method of production. Starting in the 1860s, various munitions works, railway companies, and modern factories that manufactured military and commercial goods were created by the Qing government and private industrialists.

Unlike native Chinese handicraft workshops, modern industry needed large amounts of capital for long periods of time. The capital demands of railroad construction and other infrastructure were even greater. But the Qing government’s deteriorating financial situation prevented it from appropriating large funds to initiate more new projects.

Incompetence of Existing Institutions

Though the existing financial arrangements previously had provided sufficient credit and transfer facilities to support domestic trade within the Chinese economy, they could hardly meet China’s new financial demands. Neither qianzhuang nor piaohao, as single proprietorships or partnerships with limited capital resources, proved able to provide funding for China’s modern adventures. To extend their business, most qianzhuang in Shanghai and other large treaty ports increasingly relied on the loans from piaohao and foreign banks for their working capital. Since these loans were made on a daily basis, qianzhuang had no choice but to make short-term loans to merchants rather than long-term loans to modern industrialists. Piaohao’s branch system dispersed their relatively greater capital base. Their extremely conservative owners failed to appreciate the potential profitability of the new opportunities and refused to provide funding to modern industrialists. Thus, until the end of the nineteenth century, qianzhuang and piaohao were rarely involved in China’s modern industry. Foreign banks were more interested in making quick profits by financing China’s international trade and providing loans to the Qing government than investing in the long-term development of industry in China. Furthermore, complicated Chinese business customs and procedures with which they were unfamiliar made the risk of industrial financing extremely high for foreign banks and thus prevented them from being a capital source for China’s new entrepreneurs.

Inspiration of Nationalism

Awareness of foreign intrusion into the Chinese financial market was another significant factor leading to the appearance of modern Chinese banks. After China’s defeat in the First Sino-Japanese War (1894–1895) the Qing government was forced to pay a war indemnity almost three times its annual revenue and had to borrow from foreign banks. The intensive struggle among foreign powers attempting to seize spheres of influence in China imprinted strong political meaning on these loans. It was often stipulated in loan agreements between foreign banks and the Chinese government that the latter had to assign special taxes or revenues earmarked as guarantees for loans (Wang 1983, 239–260). Many Chinese officials and intellectuals saw the situation as a sign of China’s possible demise.

The establishment of modern Chinese banks was seen as an important way to protect China from economic exploitation and invasion by foreign powers. As Sheng Xuanhuai, the founder of the first Chinese bank, said, “Should China not establish its own bank, [foreign powers] would seize all China’s profit and power” (Cheng 2007, 24). Many influential Chinese had highly appraised the bank’s role in supporting the state treasury and facilitating economy. They believed that China could not be wealthy and powerful without modern industry, but modern industry was not possible without the modernization of China’s financial institutions.
Expansion and Privatization

The Chinese nationalism triggered by the 1911 Revolution and the May Fourth demonstrations of 1919 greatly stimulated modern Chinese banking; immediately after the inauguration of the new Republican government, modern banks mushroomed throughout the country. While the power of government-owned banks declined due to government corruption and mismanagement, private banks and privatized state banks emerged as the backbone of Chinese banking. The most prominent were the Bank of China, the Bank of Communications, the so-called Three Southern Banks (Shanghai Commercial and Savings Bank, Zhejiang Industrial Bank, and National Commercial Bank), and Four Northern Banks (Jincheng Banking Corporation, Continental Bank, Yanye Commercial Bank, and China & South Sea Bank). Private banks dominated modern Chinese banking before the Beijing government was eliminated in 1928.

With China’s political unification under the Nationalist government, piaohao almost disappeared from the scene, while those of foreign banks and qianzhuang showed only a moderate expansion. Modern Chinese banks, however, experienced a quantitative expansion as well as a qualitative improvement, more than doubling their paid-up capital and reserve funds, tripling their loans, and quadrupling their deposits from 1927 to 1936. The banknotes they issued increased even more than five times. By 1936, modern Chinese banks held 81 percent of China’s capital power including paid-up capital, deposits, and circulated notes (Cheng 2007, 78). By 1937, the total assets of modern Chinese banks reached more than 7.27 billion fabi (Cheng 2007, 69). (In 1935 the central government prohibited the use and ownership of silver coins and

For centuries Chinese money consisted of circular coins with a square hole in the center to facilitate their being transported on a string. issued the fabi as China’s legal tender note; fabi were replaced by jinyuanjuan [golden yuan] in 1948.)

**Change of Power Balance in the Chinese Financial Market**

The expansion of modern Chinese banks finally changed the balance of power in the Chinese financial market. Gone forever was the domination of piaohao, qianzhuang, and foreign banks in China’s financial market, thanks to the development of modern Chinese banks. Had not the development been brutally interrupted by the Japanese invasion of China, modern Chinese banks would have had the opportunity to make even further progress and greater contributions to the development of the modern Chinese economy.

**Why Modern Banks Succeeded**

While the many historical factors discussed above contributed to the advancement of modern Chinese banks throughout these years, the most pivotal but least-studied factor actually lies embedded in these banks themselves.

![The Hong Kong and Shanghai Banking Corporation, the Bund, Shanghai, China, c. 1931. Stereographic print.](image)

Although the relationship between banks and government was full of complications, and some government policies favored the improvement of the modern banking system, the government played a very limited role in this entire process.

By the middle of the 1930s, about three-quarters of the total capital and more than 80 percent of the total assets of modern Chinese banks were concentrated among a score of principal banks. The Bank of China, Bank of Communications, the Southern Three, and Northern Four banks did the best. The total assets of these nine banks reached almost 3 billion fabi. Together these nine banks conducted about 60 percent of the loans and deposits and made up 54 percent of the assets of all Chinese banks (Cheng 2007, 70). Decisions and policies made by these principal banks largely explain why the modern Chinese banks could succeed in those years.

**Adopting Western Business Methods**

Credit for the success of these banks should be largely attributed to a group of prominent bankers who were in charge of these banks for most of the time during this period. As a group of Chinese entrepreneurs, they shared native-place ties and similar educational backgrounds. All of them had a solid Chinese classical education, while the majority had gone abroad to study at Western or Japanese colleges before starting their banking careers. Armed with knowledge of both the Western and Chinese business worlds, these bankers masterfully combined modern banking business techniques with China’s indigenous business traditions. Adjusting to the changing financial market, these people constantly introduced reforms into their banks’ business practices and management.

**Overcoming Old Habits**

A bank functions as a bank only when it starts to do business with its customers’ money. Attracting deposits for reinvestment is therefore the key to a bank’s business. To do so, however, China’s new banks had to discourage the age-old Chinese habits of hoarding gold and silver—something that neither the piaohao nor the qianzhuang had attempted. Piaohao were uninterested in
attracting deposits because their monopoly on domestic remittances already gave them access to considerable amounts of floating funds that could be used to make loans and were free of interest charges. *Qianzhuang*, for their part, usually did not accept, let alone try to attract, deposits from common people, unless the depositors were the bank manager’s relatives or friends.

Modern Chinese banks, by contrast, envisioned deposits as their lifeline and went to great lengths to persuade people of the advantages they would gain by earning interest under the guidance of the new banks rather than letting money languish hidden in drawers in their homes or buried in the ground. Various saving accounts were designed to meet different customers’ requirements. By 1936, modern Chinese banks attracted more than 4.55 billion fabi of deposits from various sources, thirty-three times more than they did in 1911 (Cheng 2007, 34, 78) thus laid the foundation for their business expansion.

**Reforms in Making Loans**

While laying the foundation for their business expansion by increasing their deposits, China’s new banks also turned their attention to loans. Unsecured credit loans were the most prevalent type of loan offered by *piaohao* and *qianzhuang*; these were extended based on a customer's business aptitude and reputation. The necessity to provide guaranty for a loan was seen as reflecting unfavorably on a person’s credit standing; only people whose credit was in question had to provide collateral to receive a loan from a bank. A merchant with good credit could easily get a loan without any material guaranty; on the other hand, a debtor would make every effort to clear his debt on time.

This manner of dealing on the basis of mutual trust was very common in the Chinese business world and for the most part worked very well, so long as the financial environment remained relatively simple. With the quantitative increase and geographic expansion of commerce in the twentieth century, however, it became extremely difficult for a lender to judge the safety of a loan based only on his clients’ personal reputation. Without material guaranties, *qianzhuang* were taking big risks in making loans. A customer’s bankruptcy often led to a *qianzhuang*’s bankruptcy, sometimes even generating a domino effect that led to a more general financial crisis.

Aware of that weakness in the traditional financial system, new banks made great efforts to avoid loans based on personal credit and to encourage loans based on material security. Instead of focusing on personal credit loans, as the native Chinese financial institutions usually did, major banks based most of their loans on the security of materials. Merchants received loans by providing collateral, and manufacturing companies got loans for their working capital by depositing their raw materials or finished goods in bank warehouses. Longer-term financing of industry was provided against the security of the mortgages on factory sites, buildings, and machinery. These loans were much safer than loans based on personal credit. Most income of these banks came from the interest on these loans.

**Reforms in Management and Structure**

Recognizing the significance of human resources in a business operation, these bankers insisted on recruiting and promoting staff according to their working abilities, instead of relying on personal connections. Various methods were designed to enhance the quality of their staff, including a series of material incentive and welfare systems, which greatly improved the working conditions of their employees.

Unlike most Chinese business firms, which functioned as groups at essentially the local or regional level, these major banks operated their business nationwide, even internationally, by establishing regional branch offices and correspondent agencies in various places. They also expanded their activities across financial fields, making more industrial loans and investing capital in numerous diverse modern ventures. By the middle of 1930s, these banks were beginning to transform into an altogether new type of institution: modern enterprises. All of these major banks were organized as limited liability companies. Their corporate structure gave professional managers great leeway in running their businesses. They took long-term growth, rather than distribution of immediate dividends, as their business goal. They adopted many ways to build a sound financial foundation for their banks. For them, the long-term development of the bank was more important than short-term dividends because the incomes, careers, and
fame of these managers relied on the expansion of their banks. It was also eventually a better way to secure the interests of stockholders.

From today’s point of view, particularly in Western countries, these approaches and business practices were commonplace. But they represented dramatic changes in the contemporary Chinese business world. Reforms in banking practices and management brought these banks substantial advantages in competing with other financial institutions, but they led the for other business leaders in adopting new corporate structures and practicing new techniques.

Maintaining China’s Indigenous Business Traditions

Although China’s new banks adopted many Western business methods, they also wisely retained many of the beneficial elements of Chinese tradition.

Each of the chief executives of all nine of China’s major banks in the early decades of the twentieth century were born, or had family roots, in Jiangsu and Zhejiang provinces. The dominance of these “Jiang-Zhe” natives (as they were called) in the Chinese financial field was not an accidental development, but one with long historical roots.

Jiang-Zhe merchants appeared in Shanghai as early as the Ming dynasty (1368–1644). Chinese traders in an alien setting tended to cluster into two kinds of groups or cliques, called bang 帮—one on the basis of native-place (common place of birth or ancestral home), and the other on the basis of common occupation. Of the ten great merchant bang that appeared during the Ming and Qing dynasties, those formed by merchants from Zhejiang and Jiangsu became the most powerful after Shanghai was opened to foreign trade in 1842. Commercial acumen was an acknowledged gift of these merchants. Though Jiang-Zhe merchants were engaged in diversified business interests in Shanghai, the greatest concentration of their resources was in banking. Shanghai finance lay primarily in their hands. Western scholars have long recognized the importance that Chinese people place on the notion of native-place ties. For Chinese people, sharing the same birthplace or the same ancestral county can reduce the psychological barriers that usually exist among businesspeople and can foster cooperation. Among merchants, those from Jiangsu and Zhejiang were famous for their fierce loyalty to their native place.

In competing with the established financial institutions, these bankers consciously used this age-old Chinese tradition of emphasizing personal guanxi (connections) to strengthen their power as a group. It was common for bankers to assume positions such as director or supervisor of the board in one another’s banks, and often these major banks helped one another to pass through difficult times. They signed contracts among themselves to open accounts in one another’s banks, and the bills and checks issued by banks that had a relationship with another could be cleared without passing regular clearinghouses. When it was necessary to send cash, the accruing fees would be waived; when one bank had an emergency, others had a responsibility to help it by advancing a predetermined amount of cash. Native-place ties were the most significant factor in establishing this kind of cooperation and special consideration.

In the absence of an effective governmental administrative apparatus for urban centers in China in the 1920s and 1930s, Chinese bankers derived considerable support from their native-place ties. They helped each other deal with expected or unexpected crises, which occurred frequently in those years. Particularly, they stood together in resisting the government’s pressure to use more financial sources for unproductive purposes.

Identification of the Individual with the Group

In China, identifying individual interest with that of the group has always been the norm; the Chinese do not value rugged individualism. China’s new bankers took full advantage of this tradition and promoted the notion that an individual worker’s interest should be identified with the bank’s interest. It was in the employees’ own best interest to work hard for the bank, the bankers pointed out, because the workers would benefit only if the bank could survive and prosper. The Shanghai Bank asked its staff to bear in mind that “the bank is me, and I am the bank.”
To encourage the sentiment expressed by this slogan, the Shanghai Bank persuaded and helped staff members to purchase bank stock. Indoctrinating their employees with the Confucian value of group consciousness was at the core of the business culture of all these banks and a vital element in their success.

**SELF-IMPROVEMENT**

Since bank staff dealt with cash every day, personal honesty was extremely important. Because the banks were such large organizations, the general managers could not directly supervise and motivate each branch manager, much less each employee. Sincerely believing in the usefulness of traditional Chinese ethics, these bankers indoctrinated their employees with Confucian principles. While strictly enforcing discipline, therefore, all major banks also asked their staff to follow certain guidelines in order to promote morality, a good work ethic, and good personal habits.

The office of the general manager of Shanghai Bank, for example, instructed its workers to adhere to the four virtues of loyalty, sincerity, honesty, and modesty and to overcome the four vices of selfishness, cheating, greed, and aggressiveness; other banks followed suit.

Also as part of such self-cultivation programs, bank employees were encouraged to improve themselves in a manner that would benefit the bank, such as learning foreign languages, becoming familiar with various foreign and domestic markets, mastering the abacus, calculating statistics, and acquainting themselves with modern legal practices. The banks encouraged their staff to learn new skills and advance their education by setting up libraries or reading rooms in the banks, inviting noted scholars to give lectures, sending staff abroad to study, and publishing relevant information in bank journals.

Self-improvement was reflected in good personal habits as well. Almost all major banks set up regulations concerning personal habits and hygiene of their staff and persuaded them to avoid bad habits. The general manager of the Jincheng Bank issued an order prohibiting his staff from participating in gambling and warned that those who violated this rule might lose their jobs. Most prominent bankers tried to set examples for their staff to view their personal integrity over material gains.

**SOCIAL RESPONSIBILITY**

From the middle of the nineteenth century onward, Chinese intellectuals believed that increasing China’s economic strength was the way to save China from miserable poverty, foreign oppression, and domestic disintegration. Bankers believed it was their responsibility to serve society and saw a possible means of national salvation in their successes. Shanghai Bank made its motto “Serving society” and invited famous scholars to lecture on and analyze how employees could help the bank facilitate it goals.

The Bank of China’s Zhang Jiaao set up three goals (which were later called “the spirit of the Bank of China”) for the staff. First, it was not enough for the Bank of China staff to provide a safe repository for the bank’s stockholders, depositors, and lenders; the bank must also seek well-being for all of society and increase the wealth and strength of the country. Second, every staff member, no matter how high or low their positions, had to be honest, selfless, and devoted to his or her work. Third, it was expected that while staff members would make no mistakes in routine transactions, they would devote serious efforts to improve their performance in furthering the bank’s reputation.

Chinese nationalism, stimulated by the establishment of the Republic of China in 1911 and the May Fourth intellectual movement, also made a strong impression on these bankers. Shanghai Bank’s Chen Guangfu told his colleagues that the bank had a special mission, which was to save China and to resist foreign economic oppression. Unlike many radical Chinese nationalists, these bankers did not oppose foreign economic presence in China. Through contact with foreigners in China and through study abroad, these bankers acquired a nationalist vision based on economic development. They admitted the superiority of Western business methods and technology and inevitably had constant contact with foreign firms, but such contact did not lessen the Chinese bankers’ sense of their national mission. In his autobiography, Zhang Jiaao stated that even if the patriotic role played by Chinese bankers was not as celebrated as that of the May Fourth student movement, their contributions to a new society in China were nevertheless important. His view was shared by the economist Ma Yinchu, who recognized
in 1933 that, "The monopoly of the foreign banks in China has declined considerably in contrast to their previous position. This is not the result from the prohibiting of their activities, from the abolition of the unequal treaties, or from the end of the extraterritoriality. It is the result of the efforts of China's new entrepreneurs who run their banking business determinedly and have overcome all sorts of hardships and deprivations. Their activity has substantially recovered China's rights and profits [from the foreign banks] and significantly improved the unequal relationship between foreigners and Chinese" (quoted in Cheng 2007, 235).

Decline of Modern Banking in China

Unfortunately, the development of modern Chinese banking was cut off by the Japanese invasion of China. In confronting the increasing Japanese military threat, the Nationalist government carried out a series of reforms to strengthen China in the middle of the 1930s. Backed by political power, the government restored its control of the Chinese financial market through various financial reforms. More state-owned banks, such as Central Bank of China, Postal Remittances & Savings Bank, and Farmers Bank of China, were established one after another or expanded. In dealing with China's financial crisis in 1935, the government launched an overall financial reform that changed China's domestic monetary base and established a managed currency system by issuing fabi as China's legal tender note. In the meantime, the government took over Bank of China, Bank of Communications, and several private banks and turned them into government-controlled banks, from which many famous bankers left or were forced to leave. Before the full-scale outbreak of the Second Sino-Japanese War in 1937 (in China, called the War of Resistance against Japan), the government had controlled over 70 percent of the assets of modern Chinese banks and established a relatively strong government-controlled central banking system.

During the wartime emergency, the Nationalist government further consolidated its financial power by establishing the General Administration of the Four Consolidated Banks (including the Central Bank of China, Bank of Communications, and Farmers Bank) to deal with all financial issues.

Modern Banking during China's Civil War Period

The wartime financial policy was continued after the war was over in 1945 and the Nationalist government executed state monopoly over 90 percent of China's banking assets. The government's control of modern banking did accomplish its immediate goal of controlling the Chinese banking industry for the imminent war against Japan. But one consequence of excessive government control was the decay of the private entrepreneurial initiative. By 1945, the total assets of all Chinese private banks were less than those of one of the larger private banks in the prewar period.

The government's total control of banking system also provided a base for government's inflation policy during China's civil war period. To meet the massive budgetary deficit caused by military expenditures, the Nationalist government circulated more and more paper money, resulting to the worst hyperinflation in Chinese history. The official exchange rate of fabi depreciated from 77,636 yuan to 1 U.S. dollar in the beginning of 1948 to 7 million yuan to 1 U.S. dollar in the middle of August (Ji 2003, 228). Attempting to control galloping inflation and to find new financial resources for the civil war, the government launched an ill-designed new currency reform and replaced fabi with jinyuanquan (or "gold yuan") on 19 August 1948. With the rapid escalation of the civil war, jinyuanquan depreciated even faster. The supply of jinyuanquan jumped 124,900 times from August 1948 to May 1949. The wholesale price index in Shanghai was more than 1.28 million times higher in the same period (Ji 2003, 234). China's financial system was totally collapsed. Certainly one important cause leading to the Nationalist government's rapid collapse after the Second World War was its ill-designed financial policy.

Modern Banking under the Communist Regime

After 1949, the Communist government went further still. It confiscated all state-owned banking institutions left by the Nationalist government and established the People's
Bank of China to manage all financial institutions and financial activities. By 1956, the socialization of all China’s private banks and other private financial institutions was accomplished. The People’s Bank of China became the sole government bank for issuing currency, making monetary policy, and granting short-term credit and loans to both public and private commercial enterprises. Over the next three decades, China’s financial institutions were no more than money collection centers and accounting houses for the large state-controlled economy. Only by middle of the 1980s had banking reform appeared on the agenda of the Chinese government.

China’s modern banking system emerged from an era in which foreign banks were dominant, developed with little government control to become state-run, and underwent reform and further foreign involvement with China’s opening and eventual accession to the World Trade Organization. As 2009 begins, China’s banks face an uncertain future, but they’ll no doubt have an impact on how the global financial crisis is resolved.

The modern banking system in China resembles banking systems in other developed countries. Both domestic and foreign-funded banks operate within the country, although foreign banks have a more difficult time getting established. Modern banking began only in the nineteenth century and has developed unevenly since then. The success of modern banking in China’s comes from a combination of tradition, innovation, socialism, and capitalism. The future, however, is less than certain.

Development of Modern Banking

Throughout the Qing dynasty (1644–1912) and until the end of the nineteenth century, the financial industry in China was dominated by foreign banks. China’s first domestic modern bank, the Imperial Bank of China, opened in Shanghai in 1897. A new type of bank was needed to meet China’s new financial demands. Since the 1860s, modern industrial practices, many borrowed from the West, had become more common in China. But modern industry needed large amounts of capital for long periods of time, which the Qing government was unable to provide and foreign banks were reluctant to lend.

The establishment of modern Chinese banks was seen as an important way to protect the country from economic exploitation and invasion by foreign powers. Foreign banks were more interested in making quick profits by financing China’s international trade and providing loans to the government than by investing in the development of industry. In addition, complicated and unfamiliar business practices made investing in industry even riskier for foreign banks.

Rising nationalism sparked by the 1911 Revolution and the May Fourth Movement of 1919 stimulated modern banking and the opening of banks. Private and privatized state banks dominated the banking systems as government-owned banks declined because of mismanagement and government corruption. The leaders were the Bank of China, the Bank of Communications, the Three Southern Banks (Shanghai Commercial and Savings Bank, Zhejiang Industrial Bank, and National Commercial Bank), and the Four Northern Banks (Jincheng Banking Corporation, Continental Bank, Yanye Commercial Bank, and China & South Sea Bank). By the mid-1930s, about 75 percent of the total capital and more than 80 percent of the total assets of modern Chinese banks were held by a handful of principal banks.
During this time the government played a limited role in the development of the banking system. The success of modern banks is attributed to a group of prominent bankers who ran the banks for most of this period. These bankers shared regional ties. They all had a solid Chinese classical education, and many had studied in the West or in Japan before starting their banking careers. They combined modern banking business techniques with China’s traditional business practices to reform the banking system. They introduced new management procedures, new types of personal and business accounts, and new bank products in the form of loans.

The development of modern Chinese banking was curtailed by the Civil War (1927–1950) and the Second Sino-Japanese War (known in China as the War of Resistance against Japan, 1937–1945). During this tumultuous time, the Nationalist government seized control of more than 90 percent of China’s banking assets to aid the war effort, which marked the beginning of the end of the private entrepreneurial initiative in China.

Banking in the PRC

Following the creation of the People’s Republic of China in 1949, all capitalist institutions and private enterprises were nationalized. By 1956 all of China’s private banks and other private financial institutions were controlled by the state. Mao Zedong instituted one central bank, the People’s Bank of China (PBC), akin to the U.S. Federal Reserve or the Bank of England. However, unlike those central banks, the PBC also took deposits, made loans, and served as a commercial bank for China. This move froze out foreign banks, which closed their Chinese operations and largely moved out of China. Over the next thirty years, China’s financial institutions acted merely as money collection centers and accounting houses for the large state-controlled economy.

When China began to open up during the 1970s and 1980s, China’s one central bank split into four specialized branches: the Bank of China (BOC), the People’s Construction Bank of China (now the China Construction Bank, or CCB), the Agricultural Bank of China (ABC), and the Industrial and Commercial Bank of China (ICBC). Each of these banks specialized in one area of China’s economy.

In 2005 and 2006, as part of the overall shift from nationalized banking, the BOC, the ICBC, and the CCB put forward initial public offerings that are now traded on the Shanghai and Hong Kong exchanges. But the divided banks also faced some challenges as foreign financial institutions took advantage of China’s new liberalization to establish representative offices on the mainland in the hopes that China would be a future market.

Foreign Banks

At first Beijing limited foreign banks to certain services, creating regulatory protection for the four state banks and smaller local banks by blocking foreign firms from getting into the domestic currency business, but that barrier was eventually removed as part of the 2001 World Trade Organization (WTO) accession deal.

Foreign banks that want to operate in China may choose from joint ventures, alliance operations, or wholly foreign-owned operations. The terms of WTO accession has meant that any qualified foreign financial institution may operate any of these types of banks in China, but application requirements and banking regulations have made it hard for many foreign banks to meet the requirements, particularly for wholly foreign-owned operations.

Since November 2006, Beijing has allowed foreign entities to operate in any region of China, under certain conditions. An applicant must go through an approval process that can take up to a year. Then the applicant has to apply for local business licenses. Foreign or joint-venture banks must be based in a regulatory jurisdiction approved by China Banking Regulatory Commission (CBRC). The bank must incorporate in China and have a minimum of registered capital of 1 billion yuan ($129.2 million) and must allocate 100 million yuan ($14.6 million) to each branch it opens. The parent enterprise of a foreign-funded or joint-venture bank must have total assets of at least $10 billion, and a foreign bank that wants to open a branch must have assets of at least $20 billion. A foreign branch bank can take time deposits only above 1 million yuan ($146,000) from Chinese citizens. Registration requirements contain loopholes that allow the CBRC to turn down any application.
Joint ventures also pose some additional challenges. While the WTO requires China to allow foreign banks to hold majority stakes in these joint operations, as of 2005, foreign partners in these ventures were limited to 25 percent shares. Joint-venture banks are subject to all the regulations governing joint ventures and foreign-owned financial institutions.

**Bank of America**

Bank of America’s wholly owned subsidiary Bank of America (Asia) was active in the Hong Kong market for ninety years. Originally founded in 1912 as the Bank of Canton (the first Chinese-owned bank in Hong Kong), it was bought by the Security Pacific National Bank in 1988 and renamed the Security Pacific Asian Bank. In 1993 Bank of America (Asia) was established after a merger between Security Pacific National Bank and Bank of America.

In 1949, when banks were nationalized in China, Bank of America closed its branch operations, but it was quick to reopen a representative office in Beijing in 1981 when China’s doors reopened to foreign banks. Bank of America (Asia) continued to grow, opening its first full consumer and commercial banking operation in Shanghai in 2004. And in January 2006, Bank of America (Asia) opened its first official Guangzhou representative office.

In 2005 Bank of America acquired a 9 percent stake in China Construction Bank, China’s second-largest bank, for $3 billion. This purchase represented the company’s largest push into China’s growing banking sector. Then in August 2006, CCB acquired Bank of America (Asia) for HK$9.7 billion (US$1.2 billion). On 12 January 2007, the official name became China Construction Bank (Asia) Corporation Limited. CCB (Asia), now a full-service...
commercial bank, has thirty branches in Hong Kong as well as corporate banking offices in Beijing, Shanghai, and Guangzhou.

**Hong Kong Shanghai Banking Corporation**

Founded in 1865 by Thomas Sutherland, a Scottish employee of the Peninsular and Oriental Steam Navigation Company, Hong Kong Shanghai Banking Corporation (HSBC) was created to help make trade between Europe, India, and China easier. HSBC is one of the few foreign-owned banks that has had a continuous presence in China, with the exception of periods of Japanese occupation. HSBC is well known internationally, with branches and holdings around the world, including the United States. While much of its twentieth-century business before the 1970s focused on inward remittances and export bills, Deng Xiaoping’s open-door policies allowed HSBC once again to pursue a wider range of banking activities.

In 1980 HSBC became the first foreign bank to open a representative office in Beijing since the founding of the People’s Republic. In 1997 it achieved another first, becoming the first foreign-owned bank to obtain a license to engage in domestic currency business. It launched yuan services in its Shanghai and Shenzhen branches in 1997 and 1998. In 2001, with China’s entry into the WTO, HSBC became the first foreign commercial bank to buy a minority stake in a local bank, acquiring 8 percent of the Bank of Shanghai in December of that year. Also in 2001 HSBC expanded its operations to Qingdao, Tianjin, and Guangzhou. In 2004 it opened operations in Suzhou, and in 2005 it expanded its operations in Chengdu and Chongqing to full branch offices.

HSBC continued to expand throughout 2007 and 2008. During those years HSBC opened branches in Shenyang, in Changsha (the first foreign bank in Hunan Province), and in Zhengzhou (the first foreign bank in Henan Province). It also launched private banking services in Beijing, Shanghai, and Guangzhou. In addition, HSBC established a locally incorporated entity on the Mainland wholly owned by the parent company. HSBC Bank (China) Company Limited started operations with a registered capital of 8 billion yuan ($1.1 billion). The bank was accepted as an overseas member of the Shanghai Gold Exchange. And HSBC joined the Credit Reporting System of the People’s Bank of China, the first foreign bank to join the system.

**Facing the Crisis**

How China’s banking system will deal with the global financial crisis that began in 2008 is difficult to gauge because of a lack of transparency in the system. Some economists believe that China’s banks are not as susceptible to worldwide pressures as banks in other countries are. Others believe that China’s banks have been just as adversely affected by bad loans and weak bottom lines as banks in other countries have been. Two things seem certain, however. The CBRC is sure to increase requirements and regulations that will affect both domestic and foreign banks. And China will work to shore up its own economy. The People’s Bank of China has already cut benchmark lending rates, and the government is investing in infrastructure improvements. Once China saves its own economy, it may become a major player in resolving the worldwide crisis.

Banque de l’Indochine was a French bank established in 1875 in Paris with branches in French colonial properties in South and Southeast Asia. From the later nineteenth and early twentieth centuries, Banque de l’Indochine was prevalent in China’s larger cities, especially in the French concessions of Shanghai and Tianjin, as well as in regions of southern China.

Founded in Paris on 21 January 1875, Banque de l’Indochine (Bank of Indochina) was a French bank that managed French colonial properties in South and Southeast Asia. Beginning in the 1890s the bank shifted its main operations from Indochina to China after France established its sphere of influence in southern China. The bank established its Hong Kong branch in 1894 and its Shanghai branch in 1899 under the Chinese name Dongfang Huili Yinháng 东方汇理银行. From 1900 to 1941 the bank represented the interests of the French government in handling the Boxer indemnity and transacted international trade between France and China.

From 1875 to 1890 Banque de l’Indochine, stepping into the vacuum created by China’s lack of a central bank, circulated its own banking notes in various denominations in China. The bank enjoyed the extraterritorial protection afforded foreign businesses, which allowed them to be protected by their own governments’ laws rather than the laws of China.

Banque de l’Indochine built a banking network in China by setting up other branches in Guangzhou (Canton), Hankou, Shenyang, Beijing, Tianjin, Zhanjiang, and Kunming. The Shanghai branch was primarily responsible for accepting deposits, granting loans, remitting currencies, discounting bills, insuring guarantees and bonds, trading foreign exchange, and handling international trade settlements. A priority of Banque de l’Indochine was financing the infrastructure of the French concession of Shanghai, such as the Shanghai Electric Power Company and Shanghai Railways. By performing commercial banking roles, the bank

French Sovereignty over Indochina

The State Department issued a policy paper on post-war Asia on 22 June 1945 that recognized French sovereignty over Indochina.

French policy toward Indochina will be dominated by the desire to reestablish control in order to reassert her prestige in the world as a great power. This purpose will be augmented by the potent influence of the Banque de l’Indochine and other economic interests . . .

increased its original paid-up capital from 8 million francs to 48 million francs, with 42 million in accumulated funds by 1910.

After the revolution of 1911 Banque de l’Indochine represented the French government in the International Banking Consortium and underwrote the £25 million reorganization loans of the Republic of China under Yuan Shikai’s regime. The bank’s paid-up capital increased from 48 million francs in 1910 to 72 million in 1919. Banque de l’Indochine became a political symbol, reflecting the French image in China.

The bank closed all branches in China after the establishment of the People’s Republic of China. Later the bank merged with the French Credit Agricole Indosuez. However, due to Chinese economic and financial reforms, the Credit Agricole Indosuez reentered China and used its old Chinese name, Dongfang Huili Yinhang, to indicate its historical banking ties with China. The bank opened its Shenzhen branch in 1982, its Shanghai branch in 1991, and its Guangzhou branch in 1994, along with its representative office in Beijing. The bank still is the largest and most important French bank in China.

Baojia

The baojia, a subbureaucratic system of hierarchically organized households, was created in the eleventh century to relieve local authorities of law enforcement and administrative functions. The system’s efficiency peaked in the Ming and Qing dynasties and was revised in the Republican era (1912–1949) by the Nationalist Party (Guomindang) to suppress Communism and train people in democratic local self-government.

During the New Policies (xinzheng) era (1069–1076) of the Northern Song dynasty (960–1126), one of China’s greatest reform periods, statesman Wang Anshi (1021–1086) is credited with creating the baojia 保甲, a system that organized the people into a hierarchy in which ten households (hui) formed a bao, fifty bao formed a large bao (da bao), and ten large bao formed a du bao; at each level a headman was selected from the constituent members of the bao. Throughout its history the structure and nomenclature of the baojia would be slightly altered, but the basic form was that ten households formed a jia, and ten jia formed a bao. The baojia became one of the most important touchstones in discussions by Chinese officials on cost-effective local government during late imperial and Republic of China (1912–1949).

At times the baojia became a catchall for local government functions such as mutual surveillance, collective responsibility, policing, bandit suppression, tax collection, census taking, militia organization, and even democratic local self-government. Historical evidence suggests that although the baojia served these various subbureaucratic functions successfully at times, its implementation was often spotty or overlooked by county magistrates who were overburdened by the complex bureaucracy of local government.

Antecedents of the Baojia

Prior to the introduction of the baojia, China had a long and rich history of hierarchically organized subbureaucratic systems serving a variety of functions and structuring the state-society relationship. China’s earliest recorded local organizational system, best described by the philosopher Mencius (372–289 BCE), is commonly referred to as the well-field (jingtian) system and purportedly existed in the early Zhou dynasty (1045–256 BCE). In this system land was the property of the state, which allowed peasants to farm eight plots surrounding a ninth in exchange for the peasants communally farming the ninth plot and remitting the profits to the state. A more extensive local subbureaucratic system—and the first hierarchical one—is found in the Rites of Zhou (Zhouti). It describes a system, demographic rather than territorial like the well-field system, functioning as a mechanism for conscription, taxation, and corvee extraction (collecting unpaid labor due from a feudal vassal to his lord), as well as for local mediation, the supervision of schools, and the promotion of agricultural production. The last of
the famous ancient subbureaucratic systems is described in the *Guanzi* (seventh century BCE). The major innovation of the Guanzi system was the concept of collective responsibility for community policing. That is, all members of the community were responsible for the conduct of each individual member.

After the unification of China by the Qin dynasty (221–206 BCE) each succeeding dynasty until the Northern Song built upon the preceding dynasty’s subbureaucratic system with structural or functional alterations responding to changing historical conditions. Not until the early years of the Tang dynasty (618–907 CE) was another major innovation introduced: the establishment of the “equal field” (*juntian*) system of land division, along with new tax and labor systems. The Tang system is notable for, among other things, being the first to require all households in China to register with the government—a key component of the later *baojia* system.

**Baojia in the Ming and Qing Dynasties**

After its development during the Northern and Southern Song (1127–1279) dynasties the *baojia* reached its mature form during the Ming (1368–1644) and Qing dynasties (1644–1912). During these two dynasties the *baojia* became, both in government writings and the minds of local magistrates, entangled with other subbureaucratic systems. These systems functioned below the official bureaucracy and organized families into hierarchical groupings designed to serve state purposes. Through the *baojia* the government co-opted family heads as representatives of the state. Through these family heads the *baojia* became responsible for keeping the peace through mutual surveillance, the pursuit and apprehension of criminals, and the settlement of local disputes. It also assumed the duties of village patrolling and self-defense and occasionally functioned as a military force, both offensive and defensive. It also served as an organization for tax collection, labor conscription, and census taking, which made it the most important system for government extraction of resources from the local levels of society. In addition to providing needed raw resources, whether physical or material, the *baojia* served many functions that the financially strapped Ming and Qing governments could not perform with remunerated officials—usually only one county magistrate, the lowest member of the official bureaucracy, was assigned to govern anywhere from tens of thousands to hundreds of thousands of people. Throughout these two dynasties the *baojia* became a key fixture in discussions on statecraft as the relatively small official bureaucracy struggled to govern a massive population with its limited resources. The *baojia* provided a popular answer as it forced the people to govern themselves and be responsible for their neighbors.

**Baojia in Republican China**

The victory of the Republican revolutionaries in 1912 brought an apparent end to the imperial *baojia* system as the new constitutional government was restructured to reflect modern world practices. In the 1920s and 1930s, however, the Nationalist Party (Guomindang 国民党)
reverted to the baojia as a resource for Communist repression in the Bandit Extermination Campaigns (1930–1934) and as a vehicle for training the people in democratic local self-government in accordance with the plans of Sun Yat-sen (1866–1925) for a democratic China. Like statecraft thinkers before them, members of the Nationalist Party saw the baojia as a fairly inexpensive solution to fundamental problems of local governance. In the end, however, the reintroduction of the baojia failed to either suppress the Chinese Communist Party or foster local democratic government.

The baojia was finally abolished in 1951 as the new Communist government in Beijing banned its existence as a remnant of a “feudal” society; however, still struggling with the problem of governing the people in local areas without the massive expenditure required, the Communists turned to the “work unit” (danwei) to serve many of the functions handled by the imperial baojia system.

Baosteel Group Corporation, located in Shanghai, is China’s largest iron and steel conglomerate, with a steelmaking capacity of about 30 million tons a year. In 2001, Baosteel became the primary supplier of steel to the Italian automaker Fiat, a step toward Baosteel’s goal of becoming a primary producer of automotive steel. In 2007, Baosteel was ranked 307 on the list of Fortune Global 500 corporations.

Officially named Shanghai Baosteel Group Corporation, Baosteel is the largest iron and steel conglomerate in China. A state-owned enterprise, Baosteel has played a significant role in the country’s economic development over the past thirty years. Ranked among the world’s top ten steel producers, the company has dominated the Chinese steel industry, accounting for some 7.8 percent of China’s total domestic steel production.

Baosteel’s Beginnings

Two events that took place in late 1978 marked the beginning of China’s reform era: the Third Plenum Session of the Eleventh Congress of the Chinese Communist Party held in Beijing, and the start of construction of a new, large-scale integrated steel plant in the Baoshan District near Shanghai. After the official conclusion of the disastrous Cultural Revolution, the new Chinese leadership under pragmatic Deng Xiaoping realized steel production was an essential component of China’s effort to modernize its industrial and economic infrastructure. Therefore a plan was approved to construct one of the most modern steel plants of the time, with advanced Japanese technology. Baoshan Iron and Steel was to be an exact copy of an existing plant in Kimitsu, Japan, operated by Nippon Steel.

Initially scheduled to be completed by 1982, the new plant suffered a series of setbacks that delayed the start of production until 1988. Soon after the facility was commissioned, however, it began to play a key role in China’s total domestic steel output. A year later, Baoshan Iron and Steel became the primary supplier to the Shanghai Automotive Industry Group Corporation. As the country’s model steel enterprise, Baoshan Iron and Steel enjoyed a special status, which enabled it to recruit from among the best engineers and managers in China, gain access to cutting-edge technology, and to receive large government contracts. For years, Baoshan Iron and Steel also greatly benefited from China’s economic expansion; indeed, steel production could not keep up with the huge demand from the domestic market.

Corporate Leadership

Among the inaugural team was Xie Qihua, a 1968 Qinghua (also spelled Tsinghua) University graduate who was recruited from the Shaanxi Steel Plant in 1978. Heading up the technical division, Xie rose through ranks to become the general manager in 1994. Under Xie, a domestic and
international marketing arm, Baosteel Group International Trade Corporation, was incorporated in 1996. This strategic move not only extended Baosteel’s marketing network throughout China, but also enabled the company to begin international expansion. Two years later, Baosteel received authorization from the State Council to acquire the Shanghai Metallurgical Holding Group and Meishan Iron and Steel Company. As a result, the Shanghai Baosteel Group Corporation was formed to become China’s leading integrated steelworks. The new conglomerate was the largest steel producer in the country, with annual steel production of nearly 30 million tons. Throughout her tenure, Xie has successfully employed acquisitions and mergers as corporate strategy for expansion. She has been nicknamed “Woman of Steel,” “Steel Queen,” and “Iron Lady.”

Challenges in the New Era

In the 1990s, Baosteel found itself in competition with many new rivals, both foreign and domestic. The Asian financial crisis of 1997 proved to be a major challenge: When the regional economies collapsed, Baosteel’s revenues also took nosedive. When China was admitted to the World Trade Organization in 2001, the country’s steel industry opened up to foreign competition, which for the first time significantly threatened Baosteel’s dominance in Chinese domestic steel market. However, through successful mergers and acquisitions, Baosteel was able to remain profitable.

Recognizing the importance of business expansion and diversification, Baosteel began to expand beyond steel production into other businesses, such as trading, finance, engineering and technology, information technology, coal chemicals, steel product deep processing, comprehensive utilization, and more. In order to compete effectively in global markets, Baosteel formed a partnership alliance in 2001 with former domestic rivals in the Shougang Group and Wuhan Iron and Steel Group Corporation. In the same year, Baosteel signed an agreement with ThyssenKrupp of Germany. Baosteel has also developed a worldwide marketing network consisting of almost twenty trading companies at home and abroad. It also collaborates with
international steel conglomerates, setting up strategic alli-
ance with them to create synergy.

**Main Products and Strategies for Expansion**

In the twenty-first century, Baosteel has begun investing in developing new steel production technologies with the goal of becoming a premier research and development base for new processes, new technologies, and new materials in China’s iron and steel industry. Its current focus is on the production of steel plate and steel tubing. Baosteel’s objectives include building itself into a production center for automotive steel, transportation steel, stainless steel, household appliance steel, electrical steel, boiler and pressure vessel steel, food and beverage packaging steel, metal product steel, special steel, and high-grade construction steel. The company’s steel is also used for tools and equipment, springs and bearings, and in the aerospace and commercial aviation industries.

Baosteel is one of the first metallurgic companies in China to obtain an ISO 14001 certification, an international environmental management standard. Recognizing the importance of environmental protection, Baosteel endeavors to be a “green” steel company. Because the air quality in the plant has been rated as clean as that of a national sightseeing resort, the company has been designated the first national industrial sightseeing destination. More significantly, through implementation of an advanced quality management system in its manufacturing process, Baosteel’s main products have been recognized by several international certification institutions. The company has received ISO 9001 certification from the BSI (British Standards Institution) and QS 9000 certification from General Motors, Ford, and Chrysler, the U.S. “big three” automakers. Baosteel’s products have also obtained recognition from special classification societies in France, Germany, Italy, Japan, and Norway. Its steel products have been exported to over forty countries and regions, including Japan, South Korea, the United States, and the European Union. In 2001, the Italian automaker Fiat chose Baosteel to be its primary supplier of steel, marking a major step forward in Baosteel’s efforts to become a supplier to the global automotive industry.

**Future Plans**

The Chinese government authorized an initial public offering of Baosteel stock on the Shanghai Stock Exchange in December 2000. Although the listing was restricted to domestic investors, it raised some RMB¥7.7 billion, the country’s largest public offering at that time. This strategic move not only had a major impact on Baosteel’s corporate culture, but also provided necessary capital for its investment in technology and future expansion. The public listing also set the stage for a future international listing, most likely on the Hong Kong Stock Exchange, which would open the company’s capital to foreign investors.

Within Baosteel, Shanghai Baoshan Iron and Steel Company generates more than half of the group’s total production. Other principal subsidiaries include Baosteel Shanghai No. 1 Iron & Steel Company, which produces mainly premium stainless steel; Pudong Steel Corporation, a plate producer; No. 5 Steel Corporation, a specialty steel products producer; and Shanghai Meishan Company and Ningbo Baoxin Stainless Steel Company. In 2007, Baosteel Group was ranked number 307 of the Fortune Global 500 corporations, with annual revenue of more than $22.6 billion. Looking forward, Baosteel has drafted ambitious plans for expansion. It is currently constructing a state-of-the-art facility in Zhanjiang, Guangdong Province, at a cost of $10 billion. Expected to come into production by 2010, this plant will make it possible for Baosteel to increase its annual production capacity to 40 million tons, a lofty goal that will make Baosteel the top steel producer in the world.

Beijing

Beijing (pronounced bay-JING) is a new city with old roots and the political and administrative heart of China. Since the economic reforms of the 1980s, and propelled by the city’s hosting of the 2008 Summer Olympic Games, Beijing has taken its place as one of the twenty-first century’s great capitals.

Beijing has long been considered one of the great cities of the world. It is the capital city of the People’s Republic of China (PRC) and the political, cultural, and educational center of the county. Beijing, with an estimated 2008 population of 17.5 million, is the second largest city in China, just behind Shanghai, whose 2008 population was estimated to be near 19 million. Before 1949, Beijing was known as Peking to the Western world. The city has been known by a number of names and has seen many changes throughout its long history.

Beijing in Ancient Times

Ji City is the first recorded name for Beijing. In 1075 BCE King Wu of the Ji Kingdom declared the city his capital. Even by then there had been a settlement on the site for a thousand years.

The kingdom of Ji was replaced by the state of Yan as the local political power sometime during the Warring States period (475–221 BCE). Ji City remained the name of the capital. The city continued to be an important strategic and administrative site for northern China’s rulers during the Qin (221–206 BCE) Han (206 BCE–220 CE) dynasties.

During the Sui dynasty (589–618 CE), the city was known as Zhou and had a population of 130,000. Tang dynasty (618–907 CE) officials called the city You. During the Sui and Tang dynasties, the city developed as a major trade center while retaining its military significance in the north of China. Rulers called for the construction of palaces, military training facilities, and temples, including the forerunner of the existing Temple of the Origin of the Dharma, a Buddhist temple in modern-day Xuanwu district.

In 938 CE the city became the southern capital of the Liao dynasty (916–1125 CE), founded by the Qidan people of Inner Mongolia. The city was renamed Nanjing, or Yanjing (Southern Place).

In the early twelfth century, the Nuzhen, or Jurchen, people of Manchuria conquered the Liao and established the Jurchen Jin Dynasty (1115–1234). In 1153 Emperor Wan Yanliang moved his capital from present-day Liaoning province to Nanjing and renamed it Zhongdu (Central Capital.) Under the Nuzhen the city became an important political capital for the first time. During this period the world-famous Lugou Qiao (Marco Polo Bridge) was built. The 235-meter (771-foot) stone-arch bridge still spans the Yongding River. The bridge is known for its 485 carved stone lions (no two alike) and as the site of the start of China’s war with Japan in 1937.

The city’s name was changed again in 1271. Kubilai Khan, founder of the Mongol Yuan dynasty (1279–1368), gave the city the Han name Dadu, or Ta-tu, (Grand...
Capital). The Mongols also called it Khanbaliq (City of the Great Khan). When the Mongols defeated the Southern Song in 1279, Dadu became the true political center of a unified China for the first time.

Massive reconstruction of the city began in 1267 and continued until 1293 as the Mongols reaffirmed their domination across China. The original site of Zhongdu was replaced by a larger rectangular area to the northeast in a beautiful lake region.

Construction of Dadu was accomplished in three major phases. The first phase was the raising of the imperial palaces, which was completed by 1274. The next phase included the building of mansions for the imperial princes, government offices, major temples, city walls and moats, and a system of streets for ordinary residences. The final phase was the digging of the Tonghui Canal, which connected the capital to the Grand Canal, a major transpiration and flood-control project.

The new city, with a population of about 500,000 people, was famous throughout the world for the splendor of its imperial buildings and its sophisticated temple art. This was a time when China was open to the world and welcomed traders and envoys from Asia, Africa, and Europe. Marco Polo visited the city and wrote admiringly of the magnificence of its palaces.

But Dadu was also a utilitarian city. It was rectangular, more than 30 kilometers (about 19 miles) in circumference, and laid out in a checkerboard pattern. Before this time, only the imperial family and high officials lived inside the city walls. After the reconstruction, ordinary people took up residence in neighborhoods organized by the hutong, the narrow streets or alleyways leading to the traditional courtyard homes so well known in later-day Beijing.

The city acquired another new name and new look during the early Ming dynasty (1368–1644). In 1368 Ming troops seized the city and renamed it Beiping (Northern Peace). Beginning in 1406 Emperor Yongle (1360–1424)
directed reconstruction and expansion of the city. Over the next fifteen years, new walls, palaces, gardens, streets, and residential areas were built. It was during this construction phase that two of the city’s most famous landmarks were built: the Tiananmen Gate and Gugong (the Forbidden City).

In 1421 Yongle transferred his capital from Nanjing to Beiping, renamed the city Beijing (Northern Capital), and moved into the newly built Forbidden City imperial palace. He was the first of fourteen Ming emperors followed by ten Qing emperors to live in the palace. The surviving complex consists of 980 buildings with 8,707 rooms and covers 74 hectares (about 183 acres). Since 1924—when the last emperor, Pu Yi (1906–1967) was driven from the palace—the Forbidden City has been under the charge of the Palace Museum. It houses an extensive collection of artwork and artifacts from the imperial collections of the Ming and Qing dynasties and is one
of the most popular tourists sites in the world. UNESCO listed it as World Heritage Cultural Site in 1987.

Almost immediately after the Manchu Qing dynasty (1644–1912) took power in China and seized the city, the name was changed to Shuntian Prefectural Capital. It was also called Jingshi. It remained China's capital throughout the Qing period. Qing builders and landscape architects added open-air pavilions, huge imperial parks, and palaces, including the well-known Summer Palace, to the cityscape. During the Qing era the population of the city grew to more than 1 million people.

Beijing's history as the imperial capital ended with the fall of the Qing and the rise of Republican China on 10 October 1911.

**TWENTIETH CENTURY**

After the collapse of the Qing dynasty, Beijing suffered along with the rest of China as various warlords struggled for power. In 1928 Nanjing was officially made the capital of China, and Beijing was designated as the Beijing Special Municipality to emphasize that the warlord government in Beijing was not legitimate. In 1930 the municipality was renamed Beiping City (Northern Peace, or North Pacified).

The city was occupied by the Japanese throughout World War II, from 1937 to 1945. During the occupation the city reverted to its former name, Beijing. Following the war Beijing's name was again changed to Beiping. In 1949, during the civil war between Nationalists and Communists, Communist forces peacefully entered Beijing. There, in Tiananmen Square, on 1 October 1949, Mao Zedong (1893–1976) proclaimed the establishment of the People's Republic of China, with Beijing as its capital city.

Beijing became the heart of China in the twentieth century. Beijing was not only the seat of government but also a hotbed of political activity. It was the center of Red Guard activity during the Cultural Revolution of the 1960s, the Beijing Spring and Democracy Wall movements of the 1970s, and the Tiananmen Square protests of the 1980s. President Richard Nixon visited the city in 1972, followed by other heads of state, sports teams from around the world, and foreign businesses and investors. For good or bad, Beijing became China’s face to the world.

By the end of the twentieth century, Beijing had been transformed, as had most of China. The economic reforms begun in the 1980s spurred rapid economic growth in Beijing. Farmland surrounding the city was incorporated and developed into housing and commercial areas, new expressways and roads crisscrossed the city, and new commercial high-rises transformed the skyline. Most parts of the old city were by then gone.

**TWENTY-FIRST CENTURY**

Many new construction and infrastructure projects were triggered by the 2008 Beijing Olympics. Visitors to Beijing saw a modern, thriving metropolis as the city opened to the world.

At the end of 2008, Beijing's population was estimated at 17.5 million, with 12.1 million registered as official residents.

*By Joan Lebold Cohen.*
residents and 5.5 million designated as floating population. More than 96 percent of Beijing’s citizens are Han people. The majority of people speak the Beijing dialect of Mandarin. Mandarin cuisine is the most popular cooking style in the city.

Beijing is in northern China, at 39°54’ N (roughly along the same latitude as Atlantic City, New Jersey) and 116°23’ E. The standard time zone for Beijing is Greenwich Mean Time +8.

Beijing occupies an area of 16,801 square kilometers (about 6,490 square miles), about the size of the entire state of Hawaii. (The land area of Los Angeles, by comparison, is about 489 square miles.) Beijing stretches 160 kilometers (about 99 miles) from east to west and more than 180 kilometers (about 112 miles) from north to south, about the distance between New York City and Philadelphia.

The city of Beijing is an independently administered municipal district, one of four in China. (The other three are Chongqing, Tianjin, and Shanghai.) Municipal districts are equivalent to provinces in the administrative divisions of the PRC. The greater Beijing area encompasses eighteen districts and counties, with Dongcheng, Xicheng, Xuanwu, Chongwen, Chaoyang, Haidian, Fengtai, and Shijingsha in the inner suburbs; and Fangshan, Mentougou, Changping, Tongxian, Shunyi, Daxing, Huairou, Miyun, Pinggu, and Yisanqing in the outer suburbs.

According to many travel companies, the top ten tourist attractions in and around Beijing are the Forbidden City, Tiananmen Square, the Great Wall, the Summer Palace, the Temple of Heaven, the Ming Tombs, the hutong tour, the Lama Temple, Beihai Park, and the Capital Museum. The National Stadium (the bird nest), built for the 2008 Olympics, is one of the city’s newest attractions.

But like all big cities in the early twenty-first century, Beijing faces many challenges. Affordable housing and a
Beijing's polluted environment are two major problems the city must solve in the coming years. The wave of commercial and industrial construction has meant the demolition of many of the traditional hutong neighborhoods, forcing people to find housing. The ongoing construction; a huge increase in the number of private cars; the common use of coal-fired boilers and furnaces; the growth of industry, especially small factories that generally do not monitor waste emissions; and the emissions from numerous heavy trucks transporting goods in, out, and around the city have all contributed to Beijing's polluted air.

City and state officials’ plans for the city’s future include cleaning up the environment, controlling development, and restricting population growth and density. The city’s unique history and status make its future a high priority for the Chinese.

Beijing Consensus
Běijīng gòngshí 北京共识

The Beijing Consensus proposes establishing China as the twenty-first-century model for economic reform in developing countries, emphasizing both China’s innovative and independent decision-making processes. It serves as a direct alternative to the earlier Western prototype of development, the Washington Consensus.

Although the term had existed in the 1990s, talk of the “Beijing Consensus” became common after the 2004 publication of a booklet by Joshua Cooper Ramo, once a partner in the consulting firm of former secretary of state Henry Kissinger. According to the Foreign Policy Centre:

A new Beijing Consensus is emerging with new attitudes to politics, development and the global balance of power. It is driven … by a ruthless willingness to innovate, a strong belief in sovereignty and multilateralism, and a desire to accumulate the tools of “asymmetric power projection.” Though it is often misunderstood as a nascent superpower, China has no intention of entering an arms race. Instead, it is intent on projecting enough “asymmetric power” to limit US political and military action in its region. Through fostering good international relations, it is safeguarding the peaceful environment needed to secure its prosperity, and deterring the attempts of some on the fringes of U.S. politics to turn it into a pariah. (Ramo, 2004)

Ramo argued in the paper that, after the collapse of the Washington Consensus, China acts as a model to developing countries, providing a more equitable paradigm of development. The Washington Consensus had first been devised in 1989 and was most famously set out in a paper by John Williamson at the Peterson Institute for International Economic Studies in Washington, D.C. In Williamson’s view, developing countries should introduce a package of reforms to restart and rejuvenate their economies. The Washington Consensus was promoted through the International Monetary Fund and the World Bank in rescue packages for countries in Latin America and, up to a point, in Africa and Asia during the 1998 Asian economic crisis.

The consensus was labeled, unfairly in Williamson’s view, as market fundamentalism. Its main prescriptions, set out in ten policy guidelines, were to impose fiscal discipline; introduce tax reform, exchange-rate controls, and public-spending restraints; liberalize the regulations for foreign direct investment; and privatize state-owned enterprises. Williamson himself was to acknowledge that naming this raft of proposals the “Washington Consensus” gave it an unwelcome political sheen.

China and India have been the two outstanding countries who have taken a much more selective approach to the ideas as originally set out in the Washington Consensus. They have introduced fiscal controls and liberalized...
foreign investment policy. China in particular has become one of the world’s largest, and most open, places for foreign direct investment, with over half a million joint ventures or wholly owned foreign ventures by the end of 2007. It has undertaken reforms of its state-owned enterprises, particularly since the 1990s under the leadership of Jiang Zemin and Zhu Rongji. According to the 2005 Organization for Economic Cooperation and Development (OECD) report on China, over half of China’s gross domestic product (GDP) growth can now be attributed to the private sector.

But in other areas, China has pursued a unique path, maintaining a very high level of state control. It has not allowed the convertibility of Chinese currency into other foreign currencies, and, while it has loosened up controls of capital outflows from China since 2005, it has maintained strict limits on how much can be used abroad. Political control from the Communist Party (through the State Council) on approving all major inward and outward investments remains strong, as does management of macroeconomic policy.

Ramo’s argument that China’s development model could be generalized to other developing nations was articulated at a time when the United States, under the Bush presidency, was suffering a decline in prestige and influence, particularly in Asia. The need for an alternative model therefore was on many policy makers’ minds. Ramo recognized the ongoing and dynamic process of innovation in the Chinese system, something that had been there since the Deng Xiaoping (1904–1997) era, with its emphasis on making practice the main criterion for policy, and willingness to experiment in order to work out what might best fit China’s circumstances. Ramo also argued that China’s emphasis on maintaining the sovereignty and independence of its own decision-making processes in the economic and financial sector was also very important.

Whether this adds up to a specific model that is relevant to other countries, rather than just blandly appealing to their nationalistic aspirations, is another matter. Many would argue that China’s economy, with its mix of inward and outward investment, agriculture and heavy industry, developed and undeveloped areas, and wealth and poverty, is so complex and unique that it offers no real framework to apply anywhere else. And even as a model for China, it sometimes lacks coherency. Countries in the Asian region have evidently been attracted by the ability of the Chinese model to deliver high levels of GDP growth, but whether they would be interested in the social and environmental costs of this is another matter.

At the heart of the Beijing Consensus is perhaps something that is not so new—the desire, both within and outside China, to act as a leader and role model for the developing world. This has been apparent before, when China presented itself as the head of nonaligned countries in the 1950s and 1960s, even during a period of increasing isolation, and again in the early 1970s, when Mao Zedong developed the theory of the Three Worlds, promoting China as the leader of that “third world.” Such a role is supported by many developing countries if only because it breaks up the monopoly on international influence and power exercised by the developed world in general, and the United States in particular. Moving beyond this to articulate how Chinese economic policy making and planning might be of use to other countries has proven far more difficult. The crisis in the global financial system from 2008 onward makes confident talk of any particular kind of model even more contentious.

The name “Bian Que”扁鹊 refers to a legendary early physician who is traditionally credited with the founding of the four methods of diagnosis in Chinese medicine—looking, listening/smelling, asking, and pulse-taking—as well as with the authorship of Nanjing (难经 Classics of Difficult Issues), an important classical text of Chinese medicine.

Early Chinese literature abounds in anecdotes about the skills of a physician named Bian Que. One such anecdote, found in Chapter 5 of Liezi (a Daoist text), tells of how he treated two male patients suffering from mind (heart)-body imbalances; one of them had a mind (heart) that was too weak and hesitant for his body, whereas the other had the opposite problem. Bian Que put both men to sleep with a drug and exchanged their hearts. The surgery was said to be so successful that each man, upon waking, headed straight back to the other’s home.

Bian Que was revered by generations of Chinese physicians as the father of diagnosis by the pulse (sphygmology), as the author of Nanjing (Classic of Difficult Issues), one of the core classical texts of Chinese medicine, and as the founder of the so-called Bian Que School, which counted among its members such renowned physicians as Hua Tuo (c. 141–208 CE). But modern scholarship has raised significant doubts as to when and where Bian Que lived or even whether he lived at all.

The first full biography of Bian Que, which was also the earliest biography of a Chinese physician, was composed by the historian Sima Qian (145?–86 BCE) in his Shiji (Records of the Grand Historian). It states that Bian Que was a man from Zheng in Bohai District (in modern-day Hebei Province) and that his real surname was “Qin” and personal name “Yueren.” It was said that he was initiated into the healing arts by an immortal who gave him many books of taboo recipes and made him take a medicinal concoction that subsequently enabled him to see objects on the other side of a wall. Thus, when examining his patients, Bian Que could see clearly the obstructions and nodes in their internal organs and vessels. Sima Qian’s biography recounts several highlights of Bian Que’s medical career, stressing his remarkable abilities as a diagnostician and acupuncturist, and these highlights provided the core of the life of Bian Que known to subsequent centuries. But as an historical document Sima Qian’s account is fraught with difficulties. First, it places Bian Que in historical contexts that stretched across vast geographical distances and spanned from the late sixth to the third centuries BCE. Second, the text ascribed to Bian Que some of the medical concepts that are now known to have been absent during those early times.

The consensus among modern scholars is that “Bian Que” was a common laudatory title given to superior healers in ancient China and that one of those receiving the title may have been Qin Yueren, whose life and accomplishments may have partially corresponded to Sima Qian’s narrative. “Bian Que,” literally referring to a bird, once was the title of the official in charge of regulating...
therapeutic stone needles (used in acupuncture and moxibustion) in the small state of Tan during the Spring and Autumn period (770–476 BCE), a title that may have totemic roots going back to the era of Yangshao culture (3200–2500 BCE). In the 1970s a stone relief was discovered in the hills of Weishan County, Shandong Province, dated to the Han dynasty (206 BCE–220 CE), depicting a figure with human’s head and bird’s body holding a stone needle to perform an acupuncture. Some scholars see this relief as a confirmation of the totemic origin of Bian Que, and the relief has since been called Bian Que Performing Acupuncture (Bian Que xing zhen tu). Some other scholars, however, suggest that “Bian Que” may have been a sinicized version of the mythical gandharvas, the human-headed birds known in India since Vedic times that were traditionally regarded as skilled physicians. In this interpretation both the bird-man disguise and some of the healing techniques of Bian Que may have resulted from maritime cultural contact between the East China coast and India that had occurred in high antiquity. Despite the mystery surrounding the historicity of Bian Que as an individual, there is no doubt that, as the stuff of legend, he enjoyed an eminence in the history of Chinese medicine unparalleled by any other physician.

Xiao Ye Ze Jing Yi, Fu Yong Guang Si, & Shan Jing Yong (Eds.). (1990). Qi de Sixiang: Zhongguo ziran guan he ren de guannian de fazhan [Ideas about Qi: The development of Chinese views of nature and humanity] Li Qing (Trans.). Shanghai: Shanghai ren min chu ban she.
A bianzhong is an ancient Chinese musical instrument comprising bells of different sizes—most often they are made of a copper, tin, and lead alloy—which are hung in an orderly way from a wooden rack and struck with a mallet. The instrument’s popularity grew after its first appearance in the Shang dynasty (1766–1045 BCE) and did not fade until the Song dynasty (960–1279).

The earliest of the ancient Chinese musical instruments called bianzhong mostly consisted of three bronze bells. As has been revealed from excavations, the number grew to five, and then to eight by mid–Western Zhou (1045–771 BCE). Bianzhong of nine or thirteen bells could be seen by the middle and late Spring and Autumn period (770–476 BCE). A bianzhong found in a tomb of the early Warring States period (475–221 BCE) has over sixty bells: the famous Zenghou Yi Mu Bianzhong (Bells from the Tomb of Marquis Yi of the Zeng State 曾侯乙墓编钟).

The Zeng bells were unearthed in the Sui County of Hubei Province, China, in 1978. The Chinese characters engraved on one of the bells disclose that the instrument was a gift to Marquis Yi 乙侯 from Xiong Zhang 熊章, King of the Chu State in 433 CE. The largest of the bells stands 153.4 centimeters (about 5 feet) tall, and the smallest stands 37.3 centimeters (about 1.2 feet) tall. The bells were hung in three tiers, the top having nineteen bells in three groups; the middle, thirty-three in three groups; and the bottom, twelve in two groups. The dimension of the set is 2.75 meters (9 feet) in height, 7.48 meters (24 feet) at the long side, and 3.35 meters (about 11 feet) at the short side. Together, the set weighs a total of 2,500 kilograms (about 5,512 pounds).

Because of the right burial conditions, the Zeng bells are still intact, capable of producing melodies. By accident, it was found that each of the bells can give two tones when struck in different locations. According to Martin Braun (2003, para. 13), a neuroscientist of music from Sweden, the craftsmanship of the instrument is such that the Zeng bells prove that about 2,500 years ago the Chinese had fifth generation, fifth temperament, a twelve-tone system in musical practice (not just in theory), a norm tone for an orchestral ensemble, an integration of fifths and thirds in tuning, and a preference of pure thirds over pure fifths. At this point in history, China was 2,000 years ahead of Europe, not only in bell casting, but also in musical acoustics.

Other bianzhong sets have been excavated, including quite a number of replicas of Zhou bells made in the Song dynasty such as: the archaistic Dasheng and Taihe series; the Number One Bianzhou of Western Han (202 BCE–CE 8), unearthed in 2000 in the Luo village of Henan Province; and a set of sixteen gold bells made in 1790 for the Qianlong emperor.

Bianzhong (bronze bells) from the Eastern Zhou dynasty (770–221 BCE) shown at the Imperial Palace, Beijing. PHOTO BY JOAN LEBOLD COHEN.

From 1703 to 1820, the Qing dynasty (1644–1912) had its summer capital in the city of Chengde, north of the Great Wall. Twice as big as the Yuanming Yuan summer palace of Beijing, Bishu Shanzhuang (Mountain Resort to Flee Summer Heat) of Chengde is today China’s largest imperial park. The imperial residence of Bishu Shanzhuang lies between the Chengde and the Waiba Miao temples (Eight Outlying temples) in a small basin crossed by the Wulie River and surrounded by mountainous terrain dominated by Chuifeng Peak. The Waiba Miao temples surround the gardens of the imperial residence. The Wulie River isolates four Waiba Miao temples from the Qing residence, which is further protected by a massive wall and a dam. Within the residence three districts extend from north to south: the Wanshu Yuan prairie around the Mongol camp; the Chinese garden district around Ruyi Lake and Island; and the three imperial palaces. The Qing court sojourned every summer in Chengde and hunted in the natural reserve of Mulan.

The Bishu Shanzhuang hills constitute the largest and most original landscape component of the imperial residence. They evoke the Changbai Shan Mountains, where the Qing dynasty had its mythical birthplace. The hill district was designed also for seclusion and contemplation. Si Mian Yun Shan, the name of a kiosk that lies at the center, epitomized Chengde’s lifestyle: isolation surrounded by clouds.

The composite style of the Chengde gardens is uniquely rich in political, aesthetic, and religious references. The built landscape results from the Kangxi and Qianlong emperors’ careful analysis of the internal spatial organization of the residence, the interactions suggested by the physical and architectural landmarks of the site of Chengde, and the universal appeal the two monarchs wanted to grant to the mountain resort.

The Kangxi emperor (1654–1722) chose the site, designed the palace and gardens, named thirty-six vistas, established a network of twenty-one hunting lodges along the road he built to link the Gubeikou gate of the Great Wall to Mulan, and authored an illustrated album of Bishu Shanzhuang.

Born in Chengde, the Qianlong emperor (1711–1799) enlarged the palace, added a library, built ten outlying temples, conceived a new series of thirty-six vistas, commissioned a number of paintings, and reedited Kangxi’s album. The Qianlong emperor used topography to magnify the unequal relationship the Qing state developed with the Tibetan Buddhist dignitaries after the Qing banners (Manchu military groups) conquered Lhasa in 1720.

The two emperors built facilities inside Bishu Shanzhuang to entertain Mongol vassals, Tibetan dignitaries, and foreign ambassadors. They erected mighty Sino-Tibetan temples around the imperial residence that competed with those of Lhasa and Shigatse.

The panorama of the Waiba Miao temples can be admired from the kiosks erected on the summits of the imperial residence. The most prominent of Waiba Miao temples, the Sumeru and Potala temples, are in Shizi Gou, the religious valley of Bishu Shanzhuang.
With its distinctive pagoda, Jinshan is the focal point of most vistas. The fabricated island is the highest landmark of the garden district. The island is surrounded by lakes and islands that reflect the cosmic jiu shan ba hai landscape archetype. A mountain at the center of eight concentric continents separated by eight seas constitutes the Buddhist universe. Jinshan is the collective name of the nine mountains of this cosmogony. In Chengde, Jinshan stood for Mount Sumeru and acted as the local substitute for the pivot of the Buddhist universe. The various heavens of Buddhist cosmology surround the towering Sumeru. The defender of Buddhism, Indra (Tiandi in Chinese), lives on its summit.

Today, the imperial gardens exude an overarching style of grandeur and significance, and manifest the territorial right and might of the administration that has restored them. In 1994 UNESCO approved the inscription of Bishu Shanzhuang and Waiba Miao temples on its World Heritage list. The short report submitted by China described the mountain resort as the crystallization of imperial garden and temple construction. Apart from its economic significance to the domestic tourist industry, Chengde serves again the political needs of an autocratic and multiethnic state.

The term “black gold politics,” which refers to the practices of an alliance of corrupt officials/elites, criminal elements, and businesspeople, has become ubiquitous in discussions of the Taiwanese government, calling into question the integrity of the powerful and exposing the dark side of Taiwan’s democratic development.

Black gold politics, or hei jin, refers to the mixture of money, politics, and corruption in Taiwan (the Republic of China). Gold suggests the power to influence politics and the economy, whereas black suggests various illicit or corrupt activities that take place: bribery, kickbacks, money laundering, electoral violence, political assassinations, bets on which candidates will win or lose electoral contests, and secretive monetary exchanges among corrupt government officials, elected politicians, gangsters, and businesspeople.

The origin of Taiwan’s black gold politics can be traced back to the 1930s and 1940s Guomindang, also known as the Nationalist Party, when its leader, Chiang Kai-shek (1887–1975) cultivated close connections with Du Yuesheng (1888–1951), the leader of the “Green Gang,” a criminal network / secret society based mainly in Shanghai. After the Guomindang withdrew from the mainland to the island of Taiwan in 1949 (where it would then be called the Kuomintang, KMT), black gold politics followed in the form of politicians who tried to maintain electoral victory by mobilizing local gangsters to campaign for them in elections and by mobilizing citizens to vote for them. After the Kuomintang members were elected to the Legislative Assembly, they paid for criminal political support by granting construction and government projects. A web of patron-client networks became firmly entrenched. In the face of mounting pressure from the dangwai (the political opposition) in the 1970s and the early 1980s, the Kuomintang relied heavily on the heidao (triads or organized crime groups) to retain its political influence in the political arena.

After Chen Shui-bian (b. 1950) of the Democratic Progressive Party (DPP) won the presidency in 2000, it was rumored that a businessperson with heidao connections, Chen Yu-hao, made a huge donation to pay down the president’s campaign expenses. Chen Yu-hao then financially supported the ticket of Kuomintang leader Lien Chan and People First Party’s James Soong during the 2004 presidential election. Chen Shui-bian’s re-election in 2004 ushered in an era of political corruption by his family. His wife, Wu Shu-jen, was found to have misused state funds by falsifying receipts and laundering money through various overseas accounts in Switzerland, Singapore, and Mauritius. Taiwan’s democratic image was dealt a severe blow because of the Chen family’s political corruption, which some commentators referred to as another example of black gold politics at the top level, where the president and his wife were not subject to internal checks and balances from the party in power. Nor were they subject to sufficient scrutiny from anticorruption and anti-money-laundering institutions. Another element in the Chen family’s corruption was the deliberate withholding of information on the family’s suspected laundering.
activities from the public by the Ministry of Justice’s Investigation Bureau director Yeh Sheng-mao. Although Yeh was indicted by Taiwan’s prosecution office, the black gold politics that plagued the former first family revealed that a minority of top-level officials colluded in self-enrichment by plundering state coffers. Chen Shui-bian’s connections with some important businesspeople in Taiwan were also called into question. The entire political-corruption scandal demonstrates the pervasiveness of black gold politics from the grassroots to top-level political echelons.

Chen was voted out of office in March 2008; on 20 May of that year, Taipei mayor and KMT chairman Ma Ying-jeou defeated his rival, Frank Hsieh of the DPP, to become the new president of Taiwan on a platform of clean government. Ma himself has not escaped the cloud of black gold politics, having been charged with money skimming in 2007 (a charge he vehemently denied, and was acquitted of later that year). In 2006, Ma told Time: “We have set up a ‘clean government’ commission to monitor our officials. When I was justice minister more than 12 years ago, I cracked down on corruption and vote-buying. I have a reputation for being clean and impartial, [and] we know that how clean we are determines our future” (Abdoolcarim and Tso 2006).

Although he was protected from charges while he was in office, former president Chen was arrested and indicted in December of 2008 for money laundering, embezzlement, and other crimes, the only former president of Taiwan ever to be jailed for corruption charges.

Blogs, or public online diaries, emerged in China in 2002 and have become very popular with Internet users, who blog to express their opinions, share their resources, and make friends. In the meantime, blogs are also having an unprecedented impact on the various aspects of society.

The word blog (bo ke in Chinese) originated from the word weblog, meaning “online diary.” The word weblog was created by Jorn Barger on 17 December 1997. The short form, blog, was created by Peter Merholz, who jokingly divided the word weblog into the clause we blog in the sidebar of his blog, Peterme.com, in 1999. Internet users quickly adopted the word as both a noun and a verb (to blog meaning “to edit one’s weblog or to post to one’s weblog”).

According to the China Internet Network Information Center (CNNIC), a blog is a kind of web space provided by a bulk synchronous parallel (BSP) computing model and registered by “netizens” (citizens of the Internet) who wish to express their own opinions and ideas on the web for others to browse. In short, a blog is a public web diary that has the function of recording and reporting. Many blogs contain personal thoughts. Other blogs are collective efforts, created by groups based on themes or shared interests.

Blog Authors and Readers in China

According to the Chinese Academy of Social Science, the average Chinese blogger is younger than thirty, and
80 percent of bloggers are under age twenty-four; 60–80 percent fall in the age group of 25–29, and 77 percent are single. In contrast to the gender ratio of general Internet users—that is, 57.2 percent are male—57 percent of bloggers are female. Most blog authors are in senior middle school or have a bachelor’s degree or above (white-collar professional workers). The main purposes of maintaining a blog, according to the CNNIC in 2006, are recording a diary, expressing one’s opinions, sharing one’s resources, and making friends.

The motivations of blog readers are a little different from those of blog authors. Most blog readers seek entertaining accounts. Others want to explore society through different perspectives, to learn and improve oneself, to gain insight into the stories behind news reports, and to find the focus of public attention. Only 42 percent of blog readers are female. The educational background of blog readers is similar to that of blog authors.

Development of Blogs in China

Blogs began in China in 2002. At first they were called “web diaries,” and the word blog was first used in China by Fang Xingdong and Wang Junxiu in July 2002. In August 2002, Fang Xingdong and Wang Junxiu coestablished the website Blogchina. In 2003 they published the first blog monograph in China, Blog—Fire-Stealer in E Era, in which they variously described a blog as a “fast and convenient knowledge-reaching-and-managing system,” a new “cooperative media,” a “non-stop web trip,” an “individual publication (community),” an “information radar system in the web,” a “manual research engine,” an “expert filter,” a “free organized web ecology,” and “the fourth web communication method after Email, BBS and ICQ.”

The year 2003 was important for the development of blogs in China; the number of users reached 200,000. In 2004 came the commercialization of the blog. In 2005 blogging spread from the elites to all netizens and non-netizens. In July 2005 the first Chinese blog movie was made. Since 2006 the number of Chinese bloggers has grown rapidly. According to the Survey Report of Chinese Internet, by the end of November 2007 the number of Chinese blogs had reached 72.82 million, whereas the number of Chinese bloggers had reached 47 million—30 million more than in August 2006. Among those bloggers 17 million were active.

The statistics of CNNIC show that only 3 percent of blogs are visited more than one hundred times per day, and 8 percent are visited more than fifty times per day. It is difficult to exploit the advertisement value of blogs if one only operates a single blog as a media forum. As bloggers become more sophisticated and prolific, the possibilities for reaping a larger profit from blog sites multiply. In September 2007 SINA blog (part of the online SINA Community) signed a contract with two thousand bloggers in China, saying that every blogger would be paid 200 RMB per 10,000 visits if the visits exceed 10,000. After the contract went into effect advertisements in SINA blogs showed a noticeable increase.

The importance of blogging in China does not lie in what information or content blogs convey but rather in the fact that blogs exist, blogs have begun to change the traditional closed and conservative ways that information is communicated in Chinese society. Blogs, by breaking through regulations and other controls, have begun to serve as advocates for individuality and personal civil rights. Although the contents of most blogs can be classified as recordings of personal feelings and private matters, technological development and increased intellectual participation gradually shift the focus of the contents to political and societal subjects that attract many more blog readers. Thus, to some degree information communicated through blogs is creating a new public media platform in China. Not only blog authors but also many blog readers have begun to comment on many aspects of China’s reforming and opening up, and in doing so enlighten ordinary citizens and government officials. With the blog’s development Chinese society has begun to embrace the core elements of liberalism, including tolerance, democracy, justice, consultation, and pluralism.

Hopes for Chinese Blogging

It is hoped that in the future blog websites in China will be more professionalized. First, the mechanics of blog self-development, such as an individual credibility system, evaluation system, and so on, will continuously
evolve. The content and format of blogs will be more enriching. Standards and rules and regulations will be monitored. Second, the social influence of blogging will increase. Blogs will become a comprehensive information platform for the whole society. Blogs will push the media industry and publishing industry to reform and will be widely utilized in government administration, businesses, education, and other structures of society. With the improvement of education and technology, the blog in China will influence not only communication but also social democracy and the spirit of liberalism. Third, blogs are becoming commercialized. Online commercials, mobile blogs, media publication and being paid for blogging, media products, and mergers, for example, will make it feasible to profit from this commercialization.

Blue Shirts Society

Lanyīshè 藍衣社

The Blue Shirts Society, composed of the young graduates of Huangpu Military Academy, were the secret agents of Nationalist China’s leader Chiang Kai-shek during the 1930s. Modeled on the European fascist practices, the Blue Shirts pledged unquestioned loyalty to Chiang and engaged in subversive activities and mass socialization, which helped to consolidate Chiang’s authoritarian rule before the Second Sino-Japanese War of 1937–1945.

In 1928 Chiang Kai-shek declared that warlordism in China had been eliminated and that China was unified under the Guomindang (GMD, Chinese Nationalist Party) government led by Chiang Kai-shek, with the capital relocated from Beijing to Nanjing. However, this national unification was nominal as warlords remained the true rulers in their respective regions, and their allegiance to the GMD government was merely symbolic. Within the Chinese government Chiang faced challenges from different cliques, and he headed the Huangpu (Whampoa) clique. At large, the Chinese Communists were growing rapidly, competing against Chiang for national power. China therefore remained divided and weak, inviting foreign intrusion, especially by the Japanese, who established a stronghold in the northeast.

To save China a group of GMD members demanded reform of the GMD and society along European fascist lines. Members of this group, aged between twenty and thirty, some of whom had received overseas education, were graduates of Huangpu Military Academy. During their Huangpu years Chiang had been their principal. They therefore naturally looked upon Chiang as their leader simply because of that affiliation. The idea of reforming the GMD came to Chiang’s attention in autumn 1931 when Liu Jianqiong, a party member, approached Chiang and brought up the idea of forming an elitist special force to assist Chiang in factional struggles.

With Chiang’s consent, these Huangpu graduates founded the Blue Shirts Society (BSS) (Lanyīshè) on 1 March 1932 in Nanjing. Its leader was He Zhonghan, and members included Liu and Dai Li; the latter was responsible for spying activities that earned him fame as “China’s Himmler.” Like its counterparts in Europe, the BSS pledged unquestioned loyalty to its leader (Chiang), promotion of militant nationalism, and fascistization of society, all deemed necessary to achieve national salvation.

The BSS was an elitist secret service organ, with its initial membership about twenty and no more than ten thousand when it was disbanded. To avoid a partisan outlook, members called themselves simply the “Blue Shirts,” identified by the color of their uniforms. To facilitate their secret activities, they operated behind the formal GMD structure. Yet, their influence was strongly felt in the police force and public security, the party, and the military. At the same time Chiang never publicly acknowledged the formal existence of the BSS.
BSS activities included subversion in the government to get rid of rival cliques, extermination of the Chinese Communists, and convert actions in the northeast to expel Japanese invaders. To strengthen Chiang’s ruling position and cultivate his cult of personality, the BSS helped to instill rank-and-file military officers with fascist ideas and organized mass socialization programs launched by Chiang in the mid-1930s, such as the New Life Movement, the National Voluntary Labor Movement, and the National Military Education Movement. The BSS paid special attention to recruiting and organizing youths.

The BSS was dissolved in March 1938 because of the Second United Front, which required that Chiang put aside the campaign against the Chinese Communists and cooperate with them to fight the War of Resistance against Japan (1937–1945, known outside China as the Second Sino-Japanese War). Nevertheless, the BSS spirit and some of its members were shortly transferred to a new organization called the “Three People’s Principle Youth Corps,” founded in May the same year.

Bo Juyi (also known as Bai Juyi) was a prolific poet, scholar, and government official active during the Tang dynasty (618–907 CE). He was widely influential for his realistic poetic style and his emphasis on social reform.

The writings of Bo Juyi (772–846 CE) stand out for their realistic style and content. The origins of Bo Juyi’s realistic approach are ascribed to his difficult early years. He witnessed life’s harshness in his youth, fleeing from battlefields and subsequently wandering from place to place with his family. He learned how to write poetry when he was five or six years old, and later achieved high official posts.

Bo did not have a smooth career in politics. In his teens, Bo resolved to take the national Jinshi examination, but was impeded by his father’s death and his mother’s illness. He finally passed the exam in 800 CE when he was twenty-nine years old and was awarded his first post. After the failure of his political patron Wang Shuwen (753–806 CE), a famous reformer of the time, Bo was demoted and thereafter transferred to various minor posts as a result of being slandered. He was hailed during his tenure as governor of Hangzhou in 822 CE for his beneficial construction work in the area. He spent his final years quietly in Luoyang.

Bo is always associated with Yuan Zhen (779–831 CE) in Chinese poetic history because the two friends wrote in a similar style and advocated social criticism as a mission for literary creation. They laid special stress on “healthy” content and unembellished style. This mission was a direct reaction to the prevalent pursuit of floridity in literature. Bo’s literary agenda was vehemently expressed in “A letter to Yuan Zhen,” which has long been seen as a manifesto on literary reform. He advocated a realist style that reflects people’s feelings, a style first demonstrated in the Book of Poetry and later considered to be a central literary tenet in normative Confucian poetics. This principle was put into practice in his poems written in the series of “neo Music Bureau songs,” a vehicle for a rejuvenation of the realism of the Han-dynasty (206 BCE–220 CE) folk-song tradition. To ensure that the social criticism in his work would be widely circulated, Bo put his compositions through a special procedure for revision before being finalized. He read them aloud to old ladies at the marketplace, making sure the language did not hinder comprehension. This practice accounts for the fluid and colloquial style in most of Bo’s poetry.

Bo did not limit himself to one style of poetry. Late in life, Bo compiled his works in four categories: “satirical,” “leisure,” “lament,” and “miscellaneous regulated verse.” “Satirical” poems carried out his mission of social criticism. “Leisure” poems express the enjoyment in his reclusive life. Of the “lamenting” works, his long poems “Lasting Regret” and “The Lute” established his monumental role in Chinese poetic history. The former is a lyrical epic on the love story between Emperor Xuanzong (reigned 712–56) and Precious Consort Yang. The latter concerns a music performance along with some autobiographical sentiments.

Bo played an important role in Chinese poetic history. His poetry and literary agenda reversed the prevalent
trend towards literary decadence, and influenced many later writers to return to the poetic simplicity espoused in Confucian doctrine.

An Epic Love Poem

“Lasting Regret,” one of Bo Jiyu’s more famous works, established his monumental role in Chinese poetic history. This is a lyrical epic on the love story between Emperor Xuanzong and Precious Consort Yang.

Monarch of Han, he doted on beauty, yearned for a bewitching temptress; Through the dominations of his sway, for many years he sought but did not find her. There was in the family of Yang a maiden just then reaching fullness, Raised in the women’s quarters protected, unacquainted yet with others. Heaven had given her a ravishing form, impossible for her to hide, And one morning she was chosen for placement at the side of the sovereign king. When she glanced behind with a single smile, a hundred seductions were quickened. All the powdered and painted faces in the Six Palaces now seemed without beauty of face.

Following the successful development of the Yangzi (Chang) and Pearl River deltas, the Bohai Economic Region, located in the northeast of China, is expected by economists to be another growing center for the Chinese economy. The Bohai area includes the cities of Beijing and Tianjin, the provinces of Liaoning, Hebei, Shanxi, and Shandong, and part of the Inner Mongolia Autonomous Region.

With the development of the Yangzi (Chang) and Pearl River deltas and several special economic zones (SEZs), such as Shenzhen and Zhuhai, the south of China has been consolidating in terms of economic prosperity. The north, as a more politically and culturally powerful area of China, with Beijing at its center, also needs to be supported economically and for sustainability. To address that concern, in October 1992 the Fourteenth People’s Congress proposed the idea of the Bohai Economic Region, and declared that region would be a priority for China’s national development plan. After years of development questions arise as to whether the Bohai Economic Region functions as well as (or better than) other economic development regions in China.

Brief Description

Bohai (Bo Sea) is a C-shaped arm of the Yellow Sea, off China’s northeast coast; the Bohai Economic Region is composed of the surrounding Liaodong Peninsula, Shandong Peninsula, and Huabei Campagna, which cover 77,000 square kilometers. It is the optimal channel through which products from the inland and northeast of China reach the Pacific and then the world. Products of the area, such as grains, poultry, and oil from Manchuria and Inner Mongolia, coal and fur from the northwest, textiles and aquatic products from the Bohai area, and even goods from Qinghai and Xinjiang, which are thousands of kilometers away, are transported through this area to the world.

Geographically speaking the Bohai Economic Region covers Bohai, the Yellow Sea, and related coastal areas located in the west Pacific, which is called the “Golden Coast” of China. The Bohai Economic Region is of vital importance in China’s economic opening to the world, especially for the north and northeast of China.

The Bohai area in general includes the directly administered (by the central government) cities of Beijing and Tianjin, the provinces of Liaoning, Hebei, Shanxi, Shandong, and part of the autonomous region of Inner Mongolia. Bohai is 1.12 million square kilometers in size, which is 12 percent of China’s total area, and contains 260 million people, which is 20 percent of the national total. The Bohai area has 157 cities, accounting for one-fourth of the cities in China. Bohai has thirteen cities with more than 1 million people. The economic volume of the Bohai Economic Circle (The Bohai Economic Region plus peripheral areas) is 45.3 percent that of the Yangzi River Delta Economic Circle (The Yangzi River delta plus peripheral areas) and is 10 percent that of the Pearl River Delta Economic Circle (The Pearl River delta plus peripheral areas).
areas). However, the area has great potential for further development.

Advantages

As an economic region in the north of China, the Bohai Economic Region had a number of advantages over others in China. The region is unique in its location, sitting in the center of the Northeast Asia Economic Circle. The region connects the Yangzi River delta, Pearl River delta, Hong Kong, Macao, Taiwan, and Southeast Asian countries in the south. It connects Korea and Japan in the east and Mongolia and Russia in the north. As the center of an economic network, the Bohai Economic Region has already attracted investment from China and abroad, which further facilitates economic cooperation with different partners.

As a booming area, the Bohai Economic Region is not only an energy consumer but also an energy provider,
which makes development of the region less dependent on the outside. The region has rich marine, mine, gas, petroleum, coal, and tourism resources and is an important agriculture base: It has 2,656 hectares of farmland, accounting for 25 percent of the national total and producing 23 percent of China’s grain.

In addition to resources, the Bohai Economic Region is rich in industry, science, and technology. It is the biggest base for both heavy industry and the chemical industry in China, with advantages in resources and market access. At the same time the region has great science and technology power. Beijing and Tianjin research institutes and universities employ one-fourth of the national total in science and technology faculty, an advantage that, when combined with rich resources, creates tremendous economic power.

Transportation is important for development and is another advantage of the Bohai region. The region has more than forty seaports, making it the most intensive seaport area in China. Its railway, road, air transportation, and communication networks also are well developed. Because of these advantages, the Bohai Economic Region is a vital distribution center sitting between the northeast, northwest, and central China and international markets.

Powerful cities working together will create an even more powerful Bohai Economic Region. Two directly administered cities, Beijing and Tianjin, are at the center; coastal cities, such as Dalian, Qingdao, Yantai, and Qinghuangdao, and capital cities farther away, such as Shenyang, Taiyuan, Shijiazhuang, and Hohhot, are at the periphery. This distribution of cities makes the Bohai Economic Region the most significant community in China in terms of politics, economy, cultural exchange, and international communication. With international economic power gradually moving to the Asia-Pacific area, Bohai is going to play an even more prominent role.

**What Has Been Achieved**

In terms of national economic development, the comprehensive capability of the region has been improved, the economic opening has been further enhanced, and its tertiary (or service) industry has been improved. Following the success of the Yangzi River delta and the Pearl River delta, the Bohai Economic Region has been predicted by economists to become a major development engine in the north and the third “pole of economic development” in China.

The Bohai Economic Region is the center of the railway network in China, with many national main railways, such as the Daqin Line for coal transport and the Jinghu Line, Jingguang Line, and Jingjiu Line for both passengers and goods. The region has 21,543 kilometers of railway, accounting for 30 percent of the national total, with a railway network density of 16.14 kilometers per 1,000 square kilometers. Also, because the region is a strategic area for coal transport, investment in railway construction has always been a focus in the region, and the network of both passenger and goods transportation is becoming more efficient.

The Bohai Economic Region also has the highest density of foreign businesses in the north of China. More than 40 percent of the research and development centers set up by multinational enterprises in China from more than eighty countries, such as Motorola, Hewlett Packard, Panasonic, Microsoft, and Fujitsu, are located in Beijing, and more than ten thousand foreign corporations have invested in Tianjin. Of the top five hundred global enterprises, more than two hundred are setting up production centers in the region. Those in Dalian have been particularly impressive.

After a decade’s development the Bohai Economic Region has been largely influenced by management, technologies, and marketing skills from foreign enterprises, which further promote marketing mechanisms, motivate the reform of existing industries, and produce economic and social benefits in the region.

**Other Regions**

The economic potentials of the Bohai Economic Region and the Yangzi River delta and Pearl River delta have already been contrasted. However, differences exist in other aspects as well.

As far as the operational environment in the Bohai Economic Region is concerned, the region still has strong and influential administrative power, but compared with Yangzi River delta and Pearl River delta methods of resource allocation, the BER’s are comparatively weak.
Such a situation is not advantageous for a region striving to be built up and improved.

As far as the business enterprise structure in the Bohai Economic Region is concerned, some enterprises have outstanding economic performance and high status. But most such enterprises are large state-owned businesses (the percentage of which in the Bohai Economic Region is higher than that in the Yangzi River delta and Pearl River delta and higher than the national average). A relatively low ratio of small- and medium-sized enterprises might not provide a stimulating environment for enterprises without adequate competition, motivation, and dynamics.

Localism in the Bohai Economic Region still prevails and is strong enough to lower the efficiency of regional development. Because of overlapping administrative managements, the coordination costs of some places in the region is still high, and the flow of capital, human resources, technology, and other producing elements is not as smooth as it should be because of the low level of market development.

Looking Ahead

Regional cooperation and development are never easy tasks; they require more than good plans, effort, and resources. Despite what has been achieved in the Bohai Economic Region, much remains to be done.

Theoretically speaking, an economic region needs two elements: principal areas, which act as leaders in economic development, and hinterlands, which provide backup for development and tie the region together. In the Yangzi River delta Shanghai undoubtedly is the principal area, whereas Suzhou, Zhejiang, Anhui, and some other areas play the hinterland role; in the Pearl River delta the principal areas are Hong Kong, Guangzhou (Canton), and Shenzhen, which are geographically adjacent, whereas the hinterland is the whole area excluding Guangdong Province. What about the Bohai Economic Region? Judging from economic volume, Beijing and Tianjin are the principal areas, but there is no hinterland; the Bohai Economic Region is a conglomeration of individually powerful places rather than an influential and cooperating region.

Planners understand this problem and want to integrate every part of the Bohai Economic Region into a truly unified region, but have had relatively little success. Localism has made it difficult enough to coordinate activities even within a province, not to mention within the region (Shandong Peninsula Production Base was under consideration for regional economic development because of its labor and geographic advantage, but ultimately nothing has been worked out).

Yet another problem of the Bohai Economic Region is environmental pollution, which is the product of the policy of “develop first and preserve later.” People look up to a sky that is gray, not blue. In addition, in an area with marine resources at its center, Chinese oceanographers have warned that the Bohai is going to be polluted within ten years if no effective measures are taken.

The Bohai Economic Region is moving ahead, developing plans and assessing resources. It has achieved goals that other economic regions have not, and has failed at goals that other economic regions have achieved. But with determination and energy, the region may yet become the third pole of economic development in China.

In the early 1920s the Russian-born Mikhail Borodin, a Bolshevik Party member, became one of Moscow’s most influential foreign operatives in China. As chief advisor to Sun Yat-sen he led the Nationalist Party (Guomindang) to adopt Leninist ideals, and went on to play a key role in Soviet secret diplomacy.

Mikhail Markovich Gruzenberg, alias Borodin, was born in Yanovichi of Vitebsk Province in Russia. He joined the Bolshevik Party in 1903. After the 1905 revolution he emigrated to the United States and set up a school for immigrant children and propagated socialism in Chicago. In the wake of the October Revolution of 1917 Borodin hurried home to place himself at the service of Communist leader Vladimir Lenin. He undertook a series of secret assignments for the Bolshevik Party in Scandinavia, Spain, Turkey, Britain, and Germany, earning the reputation of being a man capable of handling all kinds of complexities.

In the early 1920s Moscow adopted a dual policy toward China, nurturing revolutionary goals and pursuing Soviet national interests. In 1923 Borodin became one of Moscow’s foreign operatives in China. After arriving in China Borodin served as the chief advisor of Sun Yat-sen, leader of the Chinese Nationalist Party (Guomindang). He guided the transformation of the Nationalist Party into a Leninist party, playing a crucial role in creating the “united front” between the Nationalist Party and the Chinese Communist Party (CCP). In 1926–27 he was a driving force behind the decisions leading to the Northern Expedition and so-called Great Revolution, aimed at defeating various warlords and achieving China’s unification. Many scholars thus believed that Borodin was an agent of the Comintern (the Communist International established in 1919 and dissolved in 1943) and that the main goal of his China mission was to “make revolution.”

New Russian and Chinese documentation reveals that the Bolshevik Party Politburo, rather than the Comintern, sent Borodin to China. Borodin’s assignments in China went far beyond “making revolution.” A principal agent of Soviet policy toward China, he followed Moscow’s instructions to coordinate his activities with Lev Karakhan, the top Soviet diplomat in China. His monthly reports to Moscow also went through Karakhan in Beijing. In addition to working with Sun, Borodin was involved in almost every important aspect of Soviet operations in China, including secret diplomacy with the northeast warlord Zhang Zuolin and the warlord government in Beijing. In May 1924 Borodin and Karakhan cooperated to make the Beijing government sign the Sino-Soviet agreement on terms satisfactory to Moscow. Consequently, the China Eastern Railway was continuously managed by the Soviets, and the Red Army remained in Mongolia.

After Sun’s death in March 1925, Chiang Kai-shek became the Nationalist Party leader. In March 1926 Chiang acted to restrict the CCP’s influence within the Nationalist Party. Because Moscow’s main strategic goal was to check Zhang Zuolin and the expanding Japanese influence in Manchuria, Borodin urged the CCP to compromise with Chiang. After Zhang expelled Karakhan from China in October 1926, Moscow appointed Borodin to be
BORODIN, Mikhail ▪ Bào Luǒtīng ▪ 鲍罗廷

the top Soviet representative in China. Borodin assumed the overall responsibilities in dealing with the Nationalist Party, the CCP, and the various warlords—including the warlord-controlled Beijing government. Following Soviet leader Joseph Stalin’s strict instructions, Borodin emphasized the importance of relying on the Nationalist Party–CCP united front. Even after Chiang’s anti-Communist coup in April 1927, Borodin obeyed Stalin and continuously made efforts to work with the Nationalist Party left wing, represented by Wang Jingwei in Wuhan, until Wang announced a split with the CCP and Moscow in July 1927. Borodin’s China mission failed.

In the same month Borodin left China. After returning to Moscow he was assigned a few insignificant positions, among them an editorship of an English-language newspaper in Moscow. He survived the Great Purge of the 1930s. However, when the Chinese Communist revolution achieved nationwide victory in 1949, he was arrested. He died in a labor camp in Siberia in October 1951.

Boxer Protocol (Xinchou Treaty) ▷
Boxer Protocol (Xinchou Treaty)

Xīn-Chǒu Tiáoyuē 辛丑条约

The Boxer Protocol was the treaty that ended the Boxer Rebellion of 1899–1900, awarding indemnities to the eleven victorious foreign powers. In 1937 Japan invoked provisions of the protocol when it invaded China.

The Boxer Rebellion of 1899–1900 is perhaps best remembered because of the twelve-article and nineteen-annex protocol, which was signed by elder Chinese statesman Li Hongzhang and representatives of eleven foreign powers in September 1901 as a peace treaty after the catastrophic event. In 1937 Japan invoked Article 9 of the protocol, which allowed foreign troops to occupy stations between Beijing and Tianjin, when Japan exploited the Marco Polo Bridge Incident to launch its invasion of China at the start of the War of Resistance against Japan (1937–1945, known outside China as the Second Sino-Japanese War). However, the pretext of the Japanese was weak because the Marco Polo Bridge was not one of the twelve stations where the foreign powers would have been allowed to deploy.

What began as a scattered targeting of Christians by the Boxers soon was generalized to the destruction of anything foreign: churches, mines, railways, and foreign institutions, which were blamed for all the hardships that China suffered. Many of the Boxers were alienated and impoverished peasants, unemployed persons who had been dismissed from the imperial troops or local militias that disbanded, or long-distance porters who had lost their jobs to the railway companies. The Qing dynasty was neutral at first, although it benefited from the Boxer slogan; “Support the Qing and eliminate foreigners!” However, in May 1900 the Qing court began to lend support to the Boxers because it believed in their power and was ready for a confrontation with the West in order to rescue something of its downtrodden prestige in the country after the Korean debacle.

Boxers Begin Siege

The rebellion itself began on 20 June when the Boxers began an eight-week-long siege against the foreign embassies in Beijing, which had been forced on China in the first place and had destroyed its worldview of the tributary
system (dating from premodern times, when foreign powers paid homage to the emperor, pledging wealth, assets, and goods in exchange for reciprocal trade agreements or special treatment) with such “barbarians” now that China had to host them in the capital. The dowager empress foolishly declared war on the foreign powers the next day and directed the provincial governors to participate. However, they knew the military might of the West and understood the scope of the looming catastrophe. Li Hongzhang, a senior official who was respected by the West because of his experience and wisdom, had fallen from grace in Beijing and was in exile in the south.

The foreign powers finally acted to extricate their embassies from the siege. The foreign powers replaced the two thousand troops who withdrew under pressure by the Boxers with an expedition of nineteen thousand soldiers, most of them Japanese because of the ability of the Japanese to bring in reinforcements from nearby Korea while the European and U.S. troops lagged behind. The expedition conquered Beijing on 14 August, and Emperor Guang Xu and the dowager empress fled to the ancient capital of Xian. Facing defeat and chaos throughout the country, Li Hongzhang, together with Governors Liu Kon-I and Zhang Zidong in the southeast, who had previously refused to join the war, in Guangzhou (Canton) signed separate settlements with the foreign consuls in their provinces in order to avert collapse of the country.

**Peace Settlement**

These leaders again came to the rescue of the now-discredited Manchu dynasty and negotiated a peace settlement in Shanghai, known as the “Boxer Protocol.”
The most humiliating terms of the protocol were those that dictated an enormous indemnity that China was forced to pay each of the eleven foreign powers, and the twelve stations on the road between Beijing and the sea that the foreign powers were permitted to occupy to defend their reinforcements should the need rise again. That is the article that Japan invoked in 1937. Other articles in the protocol were a burden, but the burden of the indemnity, which held China’s budget hostage to foreigners for many years, was probably the most oppressive.

However, one can see some positive outcomes of the rebellion and the protocol: The Boxers proved that China could fight courageously against the West, and the protocol avoided the partitioning of China. Because the Manchus were now repudiated as foreigners who let the dynasty fall to the pressure of the West, the Chinese proved that they were capable of forming a patriotic front. This confidence was picked up by a new type of leader, Sun Yat-sen, who began to explore alternative forms of government after it became obvious that the dynasty was falling.

Boxer Rebellion
Yihétuán Yùndòng 义和团运动

The Boxer Rebellion of 1899–1900 was a bloody uprising against Western imperialism in north China. The Boxers, a group known for their expertise in the martial arts, targeted both foreigners and Chinese Christians. Foreign troops were sent in to put down the rebellion, resulting eventually in even more foreign control over the Chinese government.

The Boxer Rebellion broke out in Shandong Province in 1899 and spread across much of north China before it ended in 1900, resulting in the deaths of hundreds of foreign missionaries and thousands of Chinese. In its aftermath foreign powers greatly increased their control over the Qing dynasty (1644–1912) court, and the partitioning of China seemed a real possibility.

The rebellion began in western Shandong among secret societies. As elsewhere in China commoners in Shandong often looked to secret societies and sectarian groups for mutual aid, religious and magical services, and martial arts training, the latter causing these groups to be labeled “Boxers.” The Boxers most prominent in the rebellion were the Boxers United in Righteousness (Yihetuan), who drew members from various groups, including the Small Sword Society (known for its invulnerability magic—the belief that potions, charms, and martial-arts rituals would protect them against bullets), and the Spirit Boxers, who provided techniques for mass spirit possession. The rebellion grew rapidly in part because of local unhappiness with the increasing power of Christian missionaries, especially German Catholics in Shandong, but above all because of the drought, floods, and growing famine in north China. As the rebellion spread it became increasingly violent and led to a number of attacks against Christian missionaries and Chinese Christians. Traditional policy for dealing with peasant rebellions called for executing the leaders and encouraging the followers to return home. In this case the policy merely encouraged the spread of the rebellion and made it more diffuse. By late 1899 the rebellion was spreading rapidly.
The court was divided on the issue of the Boxers, with some officials favoring support because the Boxers’ slogan, “Support the Qing, destroy the foreign,” suggested that the Boxers’ popular antiforeignism could be used for the court’s benefit.

**Foreign Guards Sent In**

As the situation became increasingly chaotic, foreign countries sent guards to their legations in Beijing. In June 1900 the Boxers cut the railway line between Tianjin and Beijing, and a force of 2,100 foreign troops was sent from Tianjin to protect the legations in Beijing. This expedition was turned back by the Boxers, convincing some officials at the court, including the empress dowager, Cixi (1835–1908), that the Boxers could in fact defeat foreign troops. Although the empress dowager apparently did not believe in the invulnerability magic that the Boxers claimed to have, she was impressed with their ability to rally mass support. On 21 June the court declared war on all Western powers, seeing the movement as a way to retaliate against increasing foreign Imperialism. This official Qing backing led the rebellion to spread rapidly across north China, but many provincial officials remained skeptical of the Boxers, and most of them made no effort to attack foreigners or to encourage the rebellion. Many foreigners and thousands of Chinese Christians were killed during the summer, mostly in Shanxi, Zhili, and Inner Mongolia.

On 4 August twenty thousand foreign troops, including British, French, American, Russian, and German, and with more than half of them from Japan, began marching toward Beijing. They had already taken the city of Tianjin back from the Boxers and Qing troops after heavy fighting, and they drove quickly toward the capital, where the foreign legations had been under siege since June. Foreign troops entered Beijing on 14 August, and members of the court fled disguised as commoners. The Boxers in the countryside dispersed rapidly, in part because the rebellion had been defeated and in part because the drought had ended. The foreign troops looted the city and launched a series of punitive expeditions into the countryside. The German troops, whose minister had been killed, were particularly interested in extracting revenge and teaching the Chinese a lesson—the two main purposes of the punitive expeditions.
In the aftermath of the rebellion the Chinese were forced to agree to the Boxer Protocols. These required China to pay the Western powers affected by the uprising an indemnity of 450 million taels of silver (although some governments later refunded some of the money), to destroy all the forts between Beijing and the sea, to allow the stationing of foreign troops along the route to the capital, and to agree to the creation of a permanent legation guard. A number of officials were to be punished, including Prince Zhuang, who was ordered to commit suicide. The civil service exams were to be suspended for five years in forty-five cities where the Boxers had been active. These provisions were important steps toward foreign control over China. The indemnity, plus interest, was a huge drain on the government, making it even more dependent on foreign loans. The demands for the punishment of officials and the suspension of exams were more intrusive involvement in the government of China than foreigners had ever demanded before, and after the rebellion foreign consuls exerted even more control over the Chinese government. The Russians had taken advantage of the rebellion to move into Manchuria, and although pressure from the other powers eventually forced Russia to leave after the rebellion, the partitioning of China—or “carving the melon,” as Chinese nationalists called it—seemed a real possibility.

Boxer Influence

The Boxers influenced China and its relationship with the outside world long after they had been dispersed. Foreigners continued to refer to the danger of “boxerism” (wild, irrational violence) as a justification for foreign power inside China. Chinese views of the rebellion were more mixed, with the anti-imperialist May Fourth reformers seeing the Boxers as an example of the feudal backwardness that was weakening China, and the Communists seeing the Boxers as an example of the power of the aroused masses and proof of the Chinese peasantry’s innate hatred of imperialism.

Boycotts and Economic Nationalism

Chinese have used economic boycotts of foreign countries for over a hundred years to protest foreign interventions and perceived humiliations. In the early twentieth century, boycotts precipitated or accompanied major turning points in China’s relations with the imperialist powers, and since the 1980s have reemerged as China has reintegrated itself economically with capitalist countries.

The boycotting of goods has figured prominently in Sino-foreign relations for more than a hundred years. Boycotts began in the first third of the twentieth century as a means of protesting against foreign powers who intervened in Chinese affairs or who were perceived to have humiliated China. As China re-integrated itself into global capitalist markets in the later twentieth century boycotts reemerged to foster Chinese economic nationalism, although the World Trade Organization, with China as a member since 2001, has tried to ensure market access to foreign goods.

Boycotts as Policy

Beginning in the early twentieth century boycotts gave rise to or occurred simultaneously with major turning points in China’s relations with the imperialist powers. There were significant boycotts in 1905, 1908, 1909, 1915, 1919, 1923, 1925, 1928, 1931, and then nearly continuously into the second Sino-Japanese War (1937–1945). The policies behind the boycotts may have even provoked the war with Japan, which sought to ensure market access.

On one level prewar boycotts followed a predictable pattern. After a specific foreign humiliation, a popular protest ensued, which included a boycott. They generally ended when government suppression from above, inertia from below, and the profit motive among merchants, who made imports irresistibly inexpensive, undermined the commitment of participants. On a deeper level these individual boycotts did not merely emerge from nowhere as an emotional response to an act of foreign aggression in China. Rather, they are best viewed as the most conspicuous aspect of a broader continuous effort to combine nascent nationalism and consumer culture by teaching Chinese to differentiate Chinese products from foreign products. Although boycotts always included opportunists, such as hooligans and petty government officials who used the events to shakedown merchants, the core supporters remained active between boycotts. Even when boycotts failed to ban the targeted imports, which they always did, they played a pivotal role in developing Chinese nationalism and anti-imperialism.

The Anti-American Boycott of 1905 institutionalized the use of boycotts in China as an expression of anti-imperialism and nationalism. The anti-American boycott of 1905 was atypical in that it began after affronts to Chinese overseas rather than infringements of Chinese sovereignty within China. Like subsequent boycotts, this one had an identifiable spark: the increasingly restrictive U.S. immigration measures applied to all Chinese. To
express their outrage and help pressure the United States, Chinese merchants in cities throughout China boycotted American products.

This boycott was critical to the development of a sustained economic nationalist movement for four reasons. First, it initiated a long series of anti-imperialist boycotts. Second, it was national in scope, with participants in at least ten provinces and many major cities throughout China and within Chinese communities abroad, such as San Francisco. Third, the boycott cut across class lines. U.S. immigration officials had mistreated all Chinese, including manual laborers and aristocrats, so all classes supported the boycott. Fourth, the boycott created new ways and co-opted others to foster popular participation, including modifying popular songs, destroying stocks of American products, soliciting pledges, tearing down advertisement posters for American goods, spreading rumors (for example, that American cigarettes contained poison), and using advertisements to identify products as Chinese and encourage their consumption.

Protestors used different media to reach as many people as possible. Newspapers targeted the cultural elite; songs, lectures, slogans, drama performances, and cartoons of mistreated Chinese reached a wider audience; and handbills, leaflets, and placards written in the colloquial language informed intermediate groups. In short, the boycott, which gradually dissolved by 1906, fostered economic nationalism among Chinese consumers and a growing sense of empowerment through consumption and nonconsumption.

The next major anti-imperialist boycott occurred in early 1908 after Chinese officials in Guangzhou seized a Japanese ship, the Tatsu Maru II, which they believed to be smuggling weapons to anti-Qing revolutionaries. The Japanese government demanded the immediate release of the ship, an indemnity, and a formal apology, which the weak Qing government agreed to. The agreement, however, angered Chinese in the south who wanted their government to stand up to the Japanese. The chamber of commerce and native-place associations in Guangzhou proposed a boycott of Japanese products until the aggregate value of the boycotted goods matched the indemnity. Longshoremen refused to unload Japanese ships, local shipping companies vowed not to use these ships, and merchants burned Japanese products. As with other boycotts, ad hoc organizations formed to support this one. The boycott spread to other cities, particularly those with populations of merchants from Guangzhou, such as Shanghai, and in overseas communities in Honolulu, Manila, and even the Japanese city of Nagasaki.

This boycott, though short-lived, further established the usefulness of boycott process by demonstrating how quickly locals formed boycott organizations of broad social coalitions. Moreover, these groups simultaneously promoted both the boycott and the development of Chinese industries. Seventy-two leading merchants in Guangzhou, for example, were asked to finance the establishment of a large commercial firm, where merchandise of every description would be collected from all over the country and sold at a designated price to encourage and to help improve Chinese industry. The boycott also broke, if only temporarily, established trade relationships. This opened up the possibility that domestic manufactures would replace Japanese imports, allowing Hangzhou umbrella manufacturers, for instance, to gain a foothold in a market dominated until then by popular Japanese-manufactured umbrellas. Above all, the boycott provided a lasting reminder that Chinese outside the government could take foreign policy into their own hands and express nationalism and anti-imperialism through commodities. The formal boycott lasted only a few months. Nevertheless, this form of protest had been introduced to new areas of China and would soon be repeated.

Boycotts and Rising Nationalism

Japan’s treatment of China during World War I, particularly its issuance of the notorious Twenty-One Demands of 1915, which initially called for the elimination of Chinese sovereignty, led to the first nationwide, prolonged boycott of Japanese goods. The lengthy negotiations over the demands gave the Chinese plenty of time to grow impatient and organize opposition. But with Japanese pressure on the Chinese government to crack down on boycotts, supporters had to turn to less explicit ways of disseminating the call to boycott by referring to Japan indirectly. In Guangzhou, for example, Chinese newspapers regularly received letters from readers offering money to support armed resistance against the “unwarranted aggression of a certain empire.” Likewise, Chinese
were enjoined not to buy “inferior products,” which along with “enemy products” became code words for Japanese goods.

The protests surrounding the Versailles Peace Conference (1919), which grew into the larger May Fourth Movement, provide another example of the how boycotts are linked and reveal the development of Chinese nationalism. As with earlier boycotts, a specific national humiliation was at the center of protests in 1919, in this case, a shift in the foreign control of Shandong Province. Since the late nineteenth century, the province had been part of Germany’s sphere of interest. During World War I, however, Japan took over and expanded the German possessions in Shandong and required China to recognize its interests there as part of the Twenty-One Demands. China had expected to recover control of the Shandong concessions as a reward for entering the war against Germany.

Woodrow Wilson’s rhetoric of self-determination heightened this expectation. However, Japan had carefully laid the groundwork for assuming control with secret agreements. The publicizing of these agreements during the Versailles Peace Conference sparked Chinese demonstrations. On 4 May several thousand students gathered at Tiananmen Square at the entrance to the Forbidden City to advocate the return of Qingdao and denounce the Versailles settlement. In the following weeks and months, the inhabitants of some two hundred Chinese cities spread over twenty provinces participated in strikes and boycotts that lasted, depending on the place, until 1920 or 1921. The protest aimed to translate humiliation into retaliation by boycotting Japanese products, ships, and currency.

New humiliations continually stoked anti-imperialist sentiments and kept the boycotts alive. Indeed, it is not clear that any boycott ever ended. In most places they
gradually declined, only to be rekindled by new humiliations in the 1920s and 1930s. These new boycotts heightened economic nationalism through increasingly violent and vigorous means.

One of China’s most famous boycotts, that of 1925, may appear unique because it was the first time two countries were boycotted at once. The demonstrations and strikes grew out of months of escalating conflict, following the death of a Chinese factory worker at the hands of his Japanese boss. On 30 May 1925, Chinese responded to the broader mistreatment of workers at a local Japanese-owned textile mill by holding a demonstration on Shanghai’s Nanjing Road. British-led police officers from the International Settlement, of which Nanjing Road was a part, fired on the crowd, killing eleven and wounding a few dozen more Chinese. Within days strikes broke out across Shanghai and spread throughout the country. In contrast to earlier actions, Chinese demonstrators explicitly targeted both the British and the Japanese. But this fact becomes less remarkable when viewing the boycott as part of a larger effort to promote economic nationalism, which had from its start stigmatized the consumption of all imports. By the same token, interpretations of the boycott of 1925 as an event run by the fledgling Communist Party, whose labor activism undoubtedly played an important role, are overly narrow.

Expanded Scope of Boycotts

By 1925 the Nationalist Party had begun to strengthen its relationship with organizations advocating economic nationalism. Boycotts in 1928 and 1931 were the most effective to date. The nationalists greatly extended the scope of these boycotts, but they never completely controlled (and certainly did not invent) these events. Indeed, proponents of economic nationalism used the nationalist government as much as the other way around. For instance, economic nationalists used an official government campaign against cigarette smoking in the mid-1930s as a pretext for confiscating only foreign cigarettes. Ultimately, heavy pressure from Japan and the policy of “first internal pacification, then external resistance” convinced nationalist leader Chiang Kai-shek (Jiang Jieshi 将介石, 1887–1975) to withdraw support for boycotts. Nevertheless, even after the nationalist government began suppressing the boycott in May 1932—attempting to ban, for instance, the popular term enemy products—many Chinese continued to pressure merchants by picketing stores, confiscating goods, sending intimidating anonymous letters and postcards, disrupting distribution channels, pasting posters on storefronts, and forcing shopkeepers to place advertisements in local newspapers in which they vowed not to sell imports.

After the establishment of the People’s Republic of China in 1949, Chinese leaders finally and completely gained control over tariffs. Within a few years, the PRC government effectively banned the importation of virtually all consumer goods, particularly those from capitalist countries. Chinese consumers had no choice but to buy Chinese. Thirty years later China dramatically changed course. With the initiation of Deng Xiaoping’s economic reforms and opening to the outside world, China slowly began to import consumer goods.

Boycotts in Modern China

Since the start of China’s market reforms in 1978, imports from capitalist countries have once again arrived in ever-greater numbers. Such imports have collided with established economic interests as well as a growing consumer movement, which is ever ready to call a boycott against companies and countries deemed to have treated Chinese consumers unfairly.

As the range and volume of imports grew, particularly with the lead up to and China’s ascension to the World Trade Organization in 2001, the tension between Chinese products and foreign products periodically reemerges for at least three reasons. First, China’s WTO commitments allowed easier market access for multinationals and rendered countless village-owned and state-owned enterprises uncompetitive, creating millions of unemployed workers. Although less visible internationally, government and academic critics remain opposed to China’s reintegration to the capitalist market. Second, a new generation of students continues to invoke the language of economic nationalism and call for boycotts, as did those protesting the U.S. bombing of the Chinese embassy in Belgrade in 1999 and the widespread boycotts of...
the French retailing giant Carrefour in China in 2008 in retaliation for the disruption of the Olympic torch relay in Paris. Finally, Chinese consumers periodically call for boycotts of specific foreign products when they feel Chinese consumers collectively have been treated poorly or differently by multinational companies.

One hundred years after the first nationwide boycotts began to popularize product nationality, and even as the WTO attempts to ensure market access to foreign products, the real and imagined nationality of products and brands still influences Chinese life.

China’s first history of the United States was written by an American missionary named E. C. Bridgman who believed that if he could impress his Chinese audience with American accomplishments, the Chinese would be more amenable to Western ideas and diplomatic practices.

Elijah Coleman (E. C.) Bridgman was a man of firsts. He was the first Evangelical Protestant missionary to China; the first Chinese expert in America; first editor of the first major journal on sinology, the Chinese Repository; author of the first book on the Chinese language; one of the first credible Chinese translators in the United States; and author of the first history of the United States written in Chinese, an important work that helped build Sino-Western relations.

Bridgman was born 22 April 1801 in Belchertown, Massachusetts. He received his education at Amherst College and Andover Theological Seminary. After he was ordained in 1829, he was appointed to China by the American Board of Commissioners for Foreign Missions, the first American Christian foreign missionary organization.

Chinese Mission

Bridgman arrived in Guangzhou (Canton) in 1830 and began his mission at a time of unrest in China, particularly in Guangzhou.

In the years preceding the First Opium War (1839–1842), relations between Westerners and Chinese had deteriorated as tensions escalated over the opium trade and as Westerners grew increasingly frustrated with China’s restrictive trade system, which required all foreign trade to be conducted exclusively in the southeastern port of Guangzhou through a small group of officially designated Chinese merchants.

Worried about the possibility of military confrontation, Bridgman and his fellow missionaries worked to break down the cultural barriers that they believed were obstructing direct communication with Chinese authorities. They thought that by transmitting Western scientific, technological, and cultural information to the Chinese, the Chinese would be sufficiently impressed with the achievements of the West and embrace more positive and productive exchanges with the foreign “barbarians.” These missionaries, along with several British and American merchants in China who offered financial support, established the Society for the Diffusion of Useful Knowledge in China (SDUKC) in November 1834. Bridgman was the first joint secretary. The society began publishing inexpensive, easy-to-read material in Chinese.

America for the Chinese

Among the works published by the SDUKC was Bridgman’s short book A Brief Account of the United States of America (Meilige heshengguo zhilue), written in Chinese. Bridgman’s work demonstrated his grasp of the Chinese language and his skill at appealing to the cultural
Bridgman began with the Christian concept of the origins of civilization, which he conveyed through typical Chinese phraseology and narrative style. In his account of the American Revolution ("Commoner Overthrow of English Rule"), Bridgman explained how the colonies grew, prospered, and expanded their trade and commerce. He described how the King of England imposed unfair taxes on the people, including the tax on China's most important export, tea, which was brought to America aboard British ships. After explaining the causes and outcome of the American Revolution, Bridgman described the important personal contributions of George Washington and how he refused to make himself king. Bridgman knew that this story would remind his Chinese readers of Yao and Shun, two venerated sage-kings of ancient China who sought the most qualified of their subjects to succeed them instead of creating a ruling dynasty.

Photograph of E. C. Bridgman.
a similar-sounding Chinese character or two. Bridgman pointed out the advantage of the phonetic alphabet over the mode of writing used by the Chinese, noting that it could be mastered even by a small child.

Bridgman devoted considerable attention to religion and morality. In a chapter titled “Distinguishing Heresy and Orthodoxy,” he hoped to attract the interest of his readers by convincing them of the simple truths and morally transforming influence of Christianity. And although much of his discussion of Christian doctrines and beliefs must have seemed bizarre or superstitious to Chinese readers, the important point implied in the title of this chapter would have been familiar to educated Chinese because it pertained to the broader context of their own religious and philosophical traditions.

Bridgman’s Legacy

Bridgman’s history was a major source of information for the first generation of Chinese scholars and officials who, because of the challenging circumstances of their times, felt compelled to learn more about the lands, customs, and ideas of their powerful Western adversaries. The 1862 version was even translated into Japanese, and for many years afterward also served as that country’s major source of information about the United States.

But Bridgman’s contributions did not end with one book. He helped to translate the bible into Chinese. He founded the Morrison Education Society, an organization that promoted Western-style education in China. In 1841 he completed a set of textbooks/teaching aids for Chinese-language learning. He helped organize the Medical Missionary Society in China. In the early 1840s, he served as an adviser and translator in American-Sino trade negotiations.

On 28 June 1845, Bridgman married Eliza Jane Gillett (1805–1871), an American Episcopalian missionary. She went on to found the Bridgman Academy in Beijing, a school for girls. They lived in Guangzhou and adopted two Chinese girls. E. C. Bridgman died in Shanghai on 2 November 1861. Both he and Eliza are buried there.

The British American Tobacco company was among the most significant of Western companies to have invested in production facilities in China during the first half of the twentieth century. By 1937 it was manufacturing annually 55 billion machine-made cigarettes, distributed largely through indigenous Chinese mercantile networks. In 1941 its assets were seized by Japan; the company was ejected from China in 1953.

The early history of the British American Tobacco (BAT) company provides an example of both successful collaboration and intense competition between Western and Chinese businesses in pre-Revolutionary China. At its zenith in 1937 BAT manufactured and distributed 55 billion machine-made cigarettes to Chinese consumers. By adroitly aligning its manufacturing facilities with an elaborate system of Chinese mercantile networks, BAT was able to peddle its cheap tobacco products extensively throughout the hinterland of the Republic of China, generating substantial revenues for the company’s shareholders and for its Chinese partners. At the same time, BAT engaged in fierce competition with independent Chinese cigarette manufacturers—Nanyang Brothers Tobacco Company being the most successful of these—throughout the first three decades of the twentieth century.

Effectively BAT sought to maintain its control over the technology and manufacturing processes while allowing indigenous merchants the opportunity to profit from their involvement in the distribution and retailing of cigarettes.

BAT had been established in London as an international joint venture between U.S. and British tobacco manufacturers in 1902. The new organization inherited a factory in Pudong, Shanghai, which one of its parent companies, W.D. & H.O. Wills, had earlier acquired. From this base the company began to develop a nationwide system of sales and production, initially dividing the country into north and south for administrative purposes and later setting up a divisional structure based on five regions (Shanghai, Hong Kong, Hankow, Tianjin, and Manchuria). In the beginning most of its Western employees were recruited from the tobacco-growing regions of the United States. The most prominent of these employees was James Augustus Thomas, who was posted to Shanghai in 1905. In turn Thomas formed a long-term working relationship with Wu Ting Seng, a Chinese merchant with close links to the Shanghai Tobacco Guild. Over time Wu’s organization—the Wing Tai Vo Tobacco Company—developed into BAT’s main partner in China, having found its initial success in the distribution of BAT’s popular Ruby Queen cigarette brand.

After World War I the London-based elements within BAT’s management strengthened their position, and from this point U.S. influence on BAT in China began to wane, other than in the area of tobacco cultivation. Although BAT itself did not grow tobacco on a commercial scale in China, it provided advice and support, along with a ready market for the leaf, and was thus responsible for the emergence of flue-cured bright leaf tobacco as a cash

Tobacco Industry in China: Better Money or Better Health?

One of the most popular and deadly habits is also the Chinese government’s highest source of income. A balance between health and wealth has been hard to come by, but remains a constant goal in China.

The tobacco industry has always been the biggest fiscal pillar for the Chinese government. In 2007, the Chinese tobacco industry, which delivered RMB 388 billion (US$51.7 billion) taxes and profits to the government, up 25% from 2006, again secured the top position on the corporate taxpayer list. 2007 was the fastest growing year for China’s tobacco industry, as a result of product mix changes and improvements, as well as expansion of premium grade cigarettes.

Smokers are addicted to cigarettes, so is the government treasury. The Chinese government has long been trying to strike a balance between responsibility for citizen health and incentives for such a profitable industry to operate.

crop in the regions of Shandong, Henan, and Anhui in the late 1910s.

BAT proved relatively adept at overcoming the political and military dislocations that beset China during the Republican period (1912–1949) and also supported famine relief schemes, partly to promote its corporate image as a responsible Chinese institution. Its operations provided substantial amounts of tax revenues, particularly in the form of transit taxes ( liken ). Despite threats of nationalization by the Republican regime, only after the incursion of the Japanese state tobacco monopoly into China after 1931 did the company find its political position undermined. In 1941, all BAT assets were seized by Japan (with whom China had been at war since 1937), and many of its Western employees were interned for the duration of the conflict. The end of the war permitted a brief renaissance for the company in China, but after the establishment of the Communist government BAT was confronted with huge tax liabilities and was ultimately forced to withdraw from the People’s Republic of China completely in 1953, retaining only its operations in the British Crown colony of Hong Kong as a legacy.

Howard COX
The British Association for Chinese Studies (BACS) is an umbrella organization composed of more than two hundred individuals and organizations from the worlds of academia, industry, government, and the media. The group was founded after the end of China’s Cultural Revolution in 1976, reflecting China’s opening to the Western world.

The British Association for Chinese Studies (BACS), known in Chinese as Yingguo Hanxue Xiehui, was founded in 1976 to promote the study in Britain of China and of Chinese culture abroad and to inform its members of current events and research in Chinese studies. Its founding coincided with the end of the Cultural Revolution, reflecting the growing accessibility of China to British scholars and students at that time. It was founded by members of a delegation of young sinologists on the staffs of universities throughout the U.K. who were invited to China by the Chinese government in April 1976. The idea of setting up a national association was developed on a plane on the flight back from China. The group included both humanities and social science scholars, setting the tone for the association as an organization catering to all aspects of Chinese studies.

BACS is a nonpolitical organization with a membership of more than two hundred individuals and organizations whose interests relate to greater China, primarily from the academic community, but also from industry, the media, and government. BACS grew in the subsequent period of greater openness of China to the outside world.

Promoting, Liaising, and Consulting

BACS has developed numerous mechanisms for promoting Chinese studies. Its school liaison officer seeks to encourage and facilitate the study of China in schools and colleges in Britain below the university level. An affiliated organization, the British Chinese Language Teachers Society, represents the interests of teachers of Chinese at the university level. BACS also encompasses the China Postgraduate Network (CPN), which provides an organizational framework for postgraduates whose research concerns China, and aims principally to disseminate information, offer advice, maintain a database of postgraduates in Britain, and pursue links with similar organizations in other countries. The CPN produces an annual newsletter, which complements the yearly bulletin published by BACS, and holds workshops and conferences for postgraduates. In 2008 the Association for Speakers of Chinese as a Second Language was launched as part of BACS. This group represents the interests and addresses the information and networking needs of those who have spent considerable time and investment learning Mandarin Chinese as a second language. BACS also runs its own website and an e-mail list to facilitate the sharing of information and views in Chinese studies.
BACS plays a role in liaising and consulting with other area studies organizations, with funding bodies, with China-related representative offices, and with government departments. It has promoted the interests and priorities of area studies in respect of British government initiatives, such as the Research Assessment Exercise, the Teaching Quality Assessment, and the HEFCE China Studies Review. It is affiliated with United Kingdom Council for Area Studies Associations and thereby contributes to the promotion of area studies within British higher education and research.

From the beginning the main event of the association has been the annual conference at which academic papers are presented by scholars from the U.K. and other countries. It has always welcomed participation by both members and nonmembers. Each year the conference is held at a venue where Chinese studies are active and arranged around a theme of academic and public interest. Since 1995, BACS has cooperated with the British Association for Japanese Studies and the British Association for Korean Studies in organizing a joint East Asian studies conference, which takes place every three years.

BACS operates in a context where alternative organizations may engage the interests, time, and energies of its members and potential members. As is the case with other area studies associations, BACS competes for potential members with other associations that represent a dominant interest in particular academic disciplines. Thus, for example, political scientists or economists with a special interest in China may find themselves torn between involvement with BACS and engagement with associations for practitioners of their disciplines. In addition, as a nonpolitical organization, BACS may not be seen as the ideal forum for potential members whose interest in China lies primarily in the direction of political engagement, whether that may be, for example, in the promotion of or opposition to communism or socialism (with or without Chinese characteristics), in the promotion of human rights or of environmental protection.

BACS Administration

BACS is a registered charity and is funded primarily by subscriptions from individual and corporate members. It also receives grants for specific purposes from the Universities’ China Committee in London, the British Academy, and the British Council, among others. BACS also administers scholarships for U.K. students to study in Taiwan.

BACS is administered by an elected committee whose members come from academia and from governmental and nongovernmental bodies involved in China. The president is usually a leading academic from within the broad range of Chinese studies. The president whose term began in 2008 is Tim Wright, Professor of Chinese Studies at Sheffield University. Recent presidents have been Don Rimmington (University of Leeds), Don Starr (University of Durham), Tao Tao Liu (University of Oxford), Delia Davin (University of Leeds), Bonnie S. McDougall (University of Edinburgh), Frank Dikötter (School of Oriental and African Studies), Stephan Feuchtwang (London School of Economics), and Harriet Evans (University of Westminster). Presidents have been drawn from a wide range of disciplines, including linguistics, literary studies, history, economics, politics, anthropology, sociology, and cultural studies.

The British Chamber of Commerce in China, based in Beijing, maintains a network for British companies doing business in China and provides information on industry, the economy, and politics in China.

The British Chamber of Commerce in China (BCCC), previously known as the "Association of British Business in China," began in 1981 but was not formally established until 1993. Based in Beijing, it seeks to provide a network for Britain to do business in China. Four other British chambers of commerce are spread across mainland China, as well as entities in Hong Kong and in Taiwan. Each chamber operates independently but cooperates on a number of issues. Members consist of British businesses and organizations of various sizes in China as well as enterprises representing businesses or organizations in China with significant U.K.-related business interests.

Like other national chambers in China (such as the French and German chambers), the BCCC provides updates and information to people involved with industry, the economy, and politics in China. The BCCC sponsors lectures, forums, and other events with politicians from the U.K. and Chinese governments, as well as with economists, consultants, and other specialists. Forums allow BCCC members to give and receive information either relating to a specific industry such as financial services or relating to issues such as corporate social responsibility (CSR) or human resources. The BCCC also helps members recruit employees.

The BCCC maintains a directory of its twenty-five hundred members across the mainland and Hong Kong and a bimonthly magazine, British Business in China, which provides information on the latest trade issues in China and highlights members' commercial successes.

Because the BCCC is based in the capital city of Beijing (the location of the British Embassy), it is able to keep close relationships with government officials from both China and the U.K. Members of the executive committee of the chamber often represent the chamber and various members at media events and discussions with other chambers in Beijing. The BCCC's relationship with the British Embassy in Beijing lets its members have direct contact with U.K. government officials in China to discuss trade issues and policies and to lobby for support. In addition, the views of British businesses are sought from chamber members when the U.K. government discusses issues of national commercial interest with the Chinese government.

The BCCC is funded by membership fees and receives no government funding. Its governance and strategy are the responsibility of the executive committee. All members of the committee occupy full-time posts elsewhere, often as senior leaders at companies such as Standard Chartered Bank, Saatchi & Saatchi, Shell, and Rolls-Royce. The executive committee also includes one representative from each of these U.K.-China commerce bodies: China Britain Business Council, U.K. Trade and Investment, the British Council, and the Confederation of British Industry. The operational running of the
chamber is carried out by the secretariat—full-time employees who deliver services for members.

The British Chamber of Commerce in China has an annual growth rate of 8–9 percent, continually attracting British organizations and introducing new services. Key persons involved with the chamber in Beijing include Henry Wang, general manager and principal service manager, Clean Coal Energy China, Shell; Richard Margolis, regional director, Greater China, Rolls-Royce; Charles Sampson, general manager, Saatchi & Saatchi; Lyn Kok, head of financial institutions in China, Standard Chartered Bank; Ian McKendrick, managing director of the British Chamber of Commerce in China; and Michael Fosh, chairman of the British Chamber of Commerce in China and chief representative of Herbert Smith.

Thousands of one-of-a-kind ritual bronzes have been excavated in China, all artifacts of the Shang dynasty (1766–1045 BCE). The sophisticated construction and often stylized designs indicate that the Shang used an advanced technology to create some of the greatest treasures of the Bronze Age in China.

The alloy of copper (usually around 80 to 85 percent), tin, and lead produces a tough and durable metal—bronze—that the Shang dynasty (1766–1045 BCE) used to develop a unique culture during Bronze Age China. Instead of making only utilitarian items from bronze, the Shang chose to cast ritual vessels as offerings to their gods and ancestors. The largest number of bronzes has been excavated at the Shang dynasty’s last royal center, Anyang, “the Yin Ruin,” in Henan Province. Many other regions within the Shang domain, or under its cultural influences, also produced bronzes with or without regional styles.

The Shang bronzes were piece-mold cast wherein the mold was made of carefully selected clay that was sculpted, incised, and polished to form inner and outer molds. After the melted alloy was poured into the mold and allowed to cool down, the molds were removed to reveal the newly designed pieces. Because the process of removing the molds destroyed them, each set could be used only once to make a single object, therefore every artifact was individually designed and cast, and no two were identical, even the ones designed as pairs.

Some of the bronzes were cast with inscriptions of their owners or symbols of a family or tribe. Often particular patterns were cast on certain parts of the vessels. The double-eyed image, which was called a mask or taotie, was commonly used; other motifs consisted of mythical animals (such as dragons and imaginary birds) and real animals including elephants, tigers, bison, cattle, fish, snakes, and owls. Geometrical patterns were also common. The combination and location of these motifs and designs suggest some cultural significance, since their patterns were used for hundreds and thousands of years; if they were not related to beliefs or customs of the Shang, the designs might have changed through the years. But their meaning is still a mystery.

Typology and Ritual Functions

Most bronzes have been excavated from large tombs of royalty and the elite; some are from sacrificial pits, and very few are from architectural remains. Museums and private collections have preserved a great number of bronzes, although many of the bronzes were originally taken from excavation sites by looters.

The earliest ritual bronze discovered so far was a type of vessel called a jue, which was used for holding liquor and might have also worked as a cup; it was excavated in 1959 from the Erlitou site in Henan Province, which was the center of the late Xia (2100–1766 BCE) and early Shang dynasties. This vessel shows a sophisticated casting technique and is elegant in design, indicating that it was not from the early stages of bronze casting.
the beginnings of China’s Bronze Age therefore depends on finding older artifacts in future excavations.

The ritual bronzes can be catalogued according to their functions: containers for cooking food, for eating, and for holding liquor and water; weapons and tools, musical instruments, and other uses. Some pieces were used as sets and in various combinations for different occasions.

There are about thirty types of ritual bronze vessels for food and drink, and many thousands of examples have been excavated. The most important vessel is a ding—both round ding and fangding (square vessels) with three or four legs have been unearthed. Fire could be lit underneath the vessels for cooking. The remains of a whole cow were found in a large-sized ding, yet the small ones functioned as bowls. Only the highly ranked elite could use ding.

Large-sized weapons have been found in the tombs of kings, queens, and military leaders. Most bronze weapons were ritual objects that were never used but only symbolized the power and position of their owners. Sets of bells and drums have been excavated as well, indicating that music was important in ritual practice.

Anyang and Regional Cultures

In the central plains—the center of the Shang culture—a clearly advancing chronology of development in techniques, styles, types, and numbers is evident from bronzes excavated at the sites of Erlitou, Erligang, and Anyang. In Anyang, the most important and the largest site of the Shang dynasty, scholars have established four periods of bronzes, along with pottery and oracle bone inscriptions. A revolution in casting technique occurred during the
thirteenth and twelfth centuries BCE: A rich style of three layers of high and low reliefs was invented. Many bronzes from this time and place were fully covered with designs. In 1976 the tomb of one of King Wuding’s consorts, Lady Hao (often referred to as General Hao, since apparently she led several battles), was excavated to much excitement: It had never been looted in antiquity and contained approximately 900 ritual bronzes with nine kinds of inscriptions. Some types of artifacts were seen for the first time during the excavation. Daggers and axes found in her tomb indicate her high position in the Shang army.

Locally made bronze vessels display significant regional character. In Xingan Dayangzhou in Jiangxi Province, ritual pits with a large number of bronzes were found. These bronzes show a clear similarity to the Shang bronzes, yet they are different in proportion, motif combination, and casting techniques.

In the southwest, at Sanxingdui in Sichuan Province, more ritual pits and altars were excavated, and large-sized bronze human figurines and human masks were found. Elongated bronze vessels that are unique to this area were unearthed also. In the northwest, small groups lived in the mountains of Shanxi, and their bronzes exhibited a strong local character also; yet the bronzes found in the far northeast regions of today’s Liaoning Province show no local distinction but are similar to what was found in Anyang. The bronzes prove that the Shang culture spread throughout China, and that the Shang had lived together with many other peoples who also made bronze ritual artifacts but retained their unique lifestyles. The ritual bronzes are the highest achievement of the Shang dynasty and exhibit the beliefs and social systems of the Shang as well as their private lives.

Through research funding, print and online publications, and expert testimony to commissions, among other activities, the Brookings Institution’s China initiative—the John L. Thornton China Center—provides analysis, facilitates dialog, and gives recommendations on issues of Chinese domestic development and implications of China’s policies for the global economy and security.

The Brookings Institution, headquartered in Washington, D.C., is a nonprofit public policy organization that conducts research and analysis on topics of global concern. The John L. Thornton China Center assesses issues in the general areas of Chinese domestic challenges, economics and trade, energy, and foreign policy. The Center opened offices in Washington, D.C., in 2006 and created the Brookings-Tsinghua Center on the campus of Tsinghua University in Beijing in 2007.

One Brookings Institution report concerning Chinese domestic challenges addresses a proposal for land reform. Cheng Li, senior fellow at the China Center, published an analysis of this proposal that focuses on China’s ability to deal with the socioeconomic consequences of incentives for land transfer and for rural laborers to move to urban areas. Another example in this context is a 2008 panel discussion of religion in China, moderated by the China Center and attended by representatives of Chinese Buddhist, Catholic, Muslim, Protest, and Daoist communities. In the area of economics and trade, a commentary on Chinese imports by Jeffrey Bader of the China Center focused on reasons for product safety issues, including fragmentation of the manufacturing sector in China. Testimony from China Center fellow Erica Downs to the United States–China Economic and Security Review Commission discussed China’s new National Energy Administration and its potential for governing the energy sector, along with an analysis of implications of how China’s efforts to secure energy abroad might affect the United States. Analyses of China’s foreign policies consider not only United States–China relations but also China’s relations with its neighbors. For example, a report by fellows of the Brookings Institution discusses potential impacts of changes in recruitment, training, and education of the Chinese military.

The Brookings Institution’s China Center is named for its benefactor. John L. Thornton, who retired in 2003 from the presidency of the Goldman Sachs Group, is chairman of the board of trustees of Brookings and is professor and director of the global leadership program at Beijing’s Tsinghua University. The first director of the China Center was Jeffrey Bader, whose government career included positions in the U.S. State Department and the U.S. Trade Representatives Office. Bader, who served as National Security Council director for Asian affairs in the Clinton administration, accepted the same position in the Obama administration in 2009.

A long march starts from the very first step.

千里之行，始于足下

Qiān lǐ zhī xíng, shǐ yú zú xià
Buddhism was introduced to China from India during the first century CE. Since then the religion has been gradually adapted to Chinese culture and society. The long process of cultural interaction and assimilation also has resulted in distinctively Chinese Buddhist schools. Today, especially in Taiwan, Buddhism continues to play a significant role in people’s spiritual and religious lives.

Buddhism in China underwent a long process of sinicization during which the imported Indian religion was adapted to the indigenous cultural milieu and became an integral part of Chinese life. In the process Buddhism gained patronage from the ruling elite and support from the common people. It also contributed significantly to Chinese culture and thought. At the same time Buddhism was profoundly transformed by Chinese culture, as can be seen in the development of the distinctively Chinese Buddhist schools and the subordination of the Buddhist sangha (monastic community) to state control and regulation. Buddhism in China, in short, represents one of the most fascinating cases of acculturation in world history.

Arrival

Buddhism arrived in China during the first century CE during the Han dynasty (206 BCE–220 CE). The Silk Roads between China and central Asia were an important route for transmitting the religion. Dunhuang, the frontier town on Han China’s northwestern border, became a great Buddhist center; many Buddhist scriptures, sculptures, and wall paintings from that period are preserved. Buddhism also reached central China via Nepal and Tibet, southwest China via Burma (Myanmar), and south China by sea from India.

At the time of Buddhism’s arrival China had already developed a highly advanced culture with sophisticated religious traditions and philosophical systems. Its two main indigenous religious traditions were Confucianism, the teaching of the Chinese philosopher Confucius (551–479 BCE), and Daoism, the teachings of the legendary Yellow Emperor (mid-third millennium BCE) and the Chinese philosopher Laozi (sixth century BCE).

The Han imperial state sponsored Confucianism, which emphasized family values, social responsibility, and the virtues of filial piety and loyalty. Buddhism, with its emphasis on monasticism, celibacy, and withdrawal from society, ran counter to Confucian ethics and therefore met resistance among the Confucian ruling elite, who saw it as subversive to the Han imperial order.

Daoism, on the other hand, although not yet a formal religion, was popular among the Chinese people because of its ideals of longevity and immortality. To help practitioners to maintain health, achieve a long life, and even become immortals, Daoism further developed many meditative techniques and respiratory exercises. It was through its alliance with Daoism that Buddhism was able to take root in China. Indeed, many of the Buddhist texts that were translated during this early stage were on the
subjects of meditation, and most of those people who helped the foreign monks translate Buddhist scriptures were Daoist practitioners.

One significant device used for translating the Buddhist scriptures from Pali and Sanskrit was called geyi (matching the meaning)—that is, rendering Buddhist teachings by borrowing the indigenous Chinese, mostly Daoist, concepts and vocabulary. For example, dao (way) was used to translate the word dharma (divine law), shouyi (guarding the One) for Buddhist meditation, and wuwei (nonaction) for nirvana (the final beatitude that transcends suffering and is sought through the extinction of desire and consciousness). Another result of the Buddhist-Daoist alliance was the theory of huahu (converting the barbarians). Accordingly, Laozi, after leaving the Western Gate on the Chinese boarder, went to India,
where he converted the barbarians and became the Buddha. Because the Buddha was but an incarnation of Laozi, it was acceptable for the Chinese to worship the Buddha and practice Buddhism.

Some Chinese converts wrote treatises to explain Buddhist teachings in a more accessible way and, on the other hand, to defend against Confucian accusations of Buddhism’s foreign origin and monastic lifestyle. The Mouzi lihuo lun (Master Mou on Disputing the Doubts [about Buddhism]), dated around the second century, is a good example of the Chinese Buddhist apologetic writings during this early stage.

**Expansion**

Buddhism offered people solace during the period of disunity that followed the fall of the Han empire. In the north the non-Chinese rulers were impressed by Buddhist culture and gave Buddhism their full support. In the south members of the elite found consolation in Buddhist religious messages, and many of the elite became interested in Buddhist metaphysics. The “Learning of Mystics” (xuanxue) emerged during this period as a result of the mixture of philosophical Daoism and the Mahayana Buddhist doctrine of emptiness. Important Mahayana scriptures such as the Vimalakirti Sutra (Scripture of the Layman Vimalakirti), the Prajna Sutras (Scriptures of the Perfection of Wisdom), and the Saddharmapundarika Sutra (Lotus Sutra), were translated and widely circulated among Chinese intellectuals. Kumarajiva (344–413 CE), a native of Kucha in central Asia, was the most important translator of his day.

Aside from scriptural translation, apocryphal texts (weijing or yijing) were composed in an attempt to increase the acceptance of Buddhism. Indian or central Asian origins were claimed for these apocryphal texts, but in fact they were produced by native Chinese. The Dasheng qixin lun (Treatise on the Awakening of Faith According to the Mahayana), for instance, is a suspected Chinese apocryphal composition of the sixth century; its discussion of mind exerted a great influence on many of the Chinese Buddhist schools, such as Huayan 華嚴 and Chan 禅.

On the popular level the Buddhist theory of karma (the force generated by a person’s actions and held to perpetuate transmigration and to determine the nature of a person’s next existence) and doctrine of impermanence gained acceptance among the common people. Many Chinese men and women joined Buddhist monastic orders, which offered a haven to those who wanted to escape wars, conscription, and corvée (unpaid) labor. By the time China was unified in 589 under the Sui dynasty (581–618 CE), Buddhism had pervaded the realm.

**Maturity**

The period of the Sui and Tang (618–907 CE) dynasties is often viewed as the golden age of Chinese Buddhism, characterized by intellectual vitality and creativity. The most famous translator was Xuanzang (d. 664), who made a pilgrimage to India and brought back to China hundreds of Buddhist scriptures. He later founded the Faxiang (Characteristics of the Dharmas or Mind-Only) school, corresponding to Indian Yogacara Buddhism. The esoteric (Tantric) forms of Buddhism were also introduced to China and flourished briefly. However, the most significant development during this period was the

---

**An historical block-print image of the Buddha.**
formation of distinctively “sinicized” Buddhist schools: Tiantai, Huayan, Chan, and Pure Land (Jingtu) all emerged with great creativity and prominence.

During this period the state also assumed control over the Buddhist sangha. The government took charge of almost all Buddhist activities; it sponsored translation projects, regulated ordination procedures, and controlled the size of the clergy through clerical examinations. Meanwhile, the monasteries were also deeply involved in local community projects, commercial activities, and charitable programs. The “transformation texts” (bianwen; stories drawn from the Buddhist scriptures) and “transformation illustrations” (bianxiang) discovered in the Dunhuang area are surviving examples of contemporary efforts to reach the Chinese people on a grassroots level.

During the late Tang dynasty, however, the expansion of the Buddhist monasteries, the growth of the clerical population, and the increasing accumulation of tax-free temple lands and wealth eventually prompted the court to suppress Buddhism. The Huichang Suppression (842–845 CE), which occurred during the reign of Emperor Wu-zong (reigned 841–846), brought empire-wide destruction of temples and shrines, confiscation of temple lands, and laicization (to put under the direction of or open to the laity) of Buddhist clergy. Although the Huichang Suppression was not the first such incident in Chinese Buddhist history (two earlier incidents occurred in 446 CE and 574–577 CE), it was the most severe, marking a turning point in the history of Chinese Buddhism. Some argue that Chinese Buddhism entered into an age of decline at this point, whereas others say that in the following centuries Chinese Buddhism took a new direction to retain its vitality and popularity.

Syncretism

After bringing an end to a century of domination by military warlords, the Song dynasty (960–1279) established a new civil order under a centralized government. The Emperor Taizu (reigned 960–975 CE) issued an imperial decree integrating Buddhism into the state’s civil order, and the first Chinese edition of the Tripitaka (the Buddhist canon) was printed in Sichuan Province from 972 to 983. Four other editions were also published during the Song dynasty.

Although the Song dynasty did not witness the emergence of new Buddhist schools, it was a period marked by doctrinal developments, institutional growth, and a tendency toward syncretism (the combination of different forms of belief or practice). After a period of decline Tiantai was revived through the editing of old texts and the composing of new ones. Tiantai also consolidated its institutional foundation by gaining imperial recognition and local support. Huayan, although it ceased to be an independent school, influenced Tiantai and Chan teachings. Pure Land Buddhism was popular among people of all social classes. Chan developed its unique identity and became the dominant form of institutional Buddhism, enjoying prominence both within clerical circles and among the secular elite.

A strong tendency toward syncretism was evident in Chinese religions from Song times onward. It was reflected in the advocacy of harmony among the various Buddhist schools and also in the promotion of “the Unity of the Three Teachings” (in other words, Confucianism, Daoism, and Buddhism). Tantric Buddhism, the Tibetan form of which flourished under the Mongol Yuan dynasty (1279–1368) and the Manchu Qing dynasty (1644–1912), held little appeal for the Chinese common people in general. Lay Buddhism, a Buddhist movement that became popular in the Song dynasty, rose to prominence under the leadership of the Ming monk Zhuhong (1535–1615) and continued to be active through the end of the nineteenth century.

Buddhist Schools

Huayan, Tiantai, Pure Land, and Chan were the most significant Buddhist schools in China. Whereas both Chan and Pure Land focused on practice, Huayan and Tiantai were doctrinal schools. Both Tiantai and Huayan built their theories of universal salvation on the doctrine of tathagatagarbha (Chinese: rulai zang, “embryo of the Tathagata [Buddha]”), or the doctrine of the Buddha-nature. The Tiantai school was named after Mount Tiantai in Zhejiang, southeast China, where its founder, Zhiyi (or Zhikai, 538–597 CE), resided. The basic text of the Tiantai school was the Lotus Sutra. Zhiyi’s most significant contribution to Chinese Buddhism was his theory of “doctrinal classification” (panjiao). He divided
the Buddha’s divergent and often contradictory teachings into chronological periods based on the Buddha’s life in an attempt to integrate them into a complex and coherent scheme. In this way Zhiyi established an eclectic school that recognized all forms of Buddhist teachings and ranked them in a hierarchical order.

Tiantai emphasizes mutual identification between all things and the absolute on the basis of the Mahayana doctrine of emptiness. The whole universe is present in a grain of sand or a drop of dew, and the wisdom of the Buddha is present in every individual’s mind.

The Huayan (garland) school was named after its scripture, the *Avatamsaka Sutra* (Chinese: *Huayan jing*). Like Tiantai, Huayan was a purely Chinese product, with no Indian counterpart. Huayan’s third patriarch, Fazang (643–712 CE), and fifth patriarch, Zongmi (780–841 CE), were the most significant masters. Fazang, who was often considered to be the real founder of the Huayan school, systematized Huayan teachings into a well-coordinated system. Zongmi synthesized Chan and Huayan teachings, and his theory of sudden enlightenment versus gradual enlightenment had significant impact on the development of Chan.

Like Tiantai, Huayan is concerned with the relationship between absolute reality and things in the phenomenal world. The entire universe is seen as a single nexus of conditions in which everything simultaneously depends on and is depended on by everything else.

Chan, the school of meditation, claims that its teaching was a silent, mind-to-mind transmission directly from the Buddha. The transmission eventually came down to Bodhidharma, who allegedly traveled from India to China around 520 CE and founded the Chan school. Chan emphasizes self-enlightenment, that is, realizing one’s inherent Buddha-nature by sitting in meditation and by practicing *gong’an* (public case). The
Linji school, well known for advocating *gong’an* meditation, and the Caodong school, well known for teaching “silent-illumination Chan” (*mozhao chan*), were the two most prominent Chan sects.

Pure Land Buddhism, on the other hand, teaches that faith in Amitâbha Buddha can lead one to be reborn in his happy land after this life and finally enter nirvana. Mindfully reciting Amitâbha’s name (the ritual is known as *nianfo* in Chinese) has been the most popular practice among the Pure Land devotees.

**Chinese Culture**

Buddhism introduced many terms to the Chinese vocabulary and led the Chinese to invent devices of phonological and grammatical analysis to deal with foreign languages. Buddhism as an organized system of religion stimulated the organization of religious Daoism into an institutional entity with its own canons, doctrinal system, and priesthood. In addition, Buddhism exerted a great influence on neo-Confucian theories of lineage transmission, mind cultivation and concentration, and attainment of sagehood, the ideal goal for neo-Confucians through spiritual cultivation and moral perfection. The Buddhist concept of karma and retribution became a dominant theme in Chinese vernacular literature, and images of Buddhist deities and figures such as the bodhisattva (deity) Avalokitesvara (Guanyin) and arhats (*lohan*, Buddhists who have reached the stage of enlightenment) were common subjects of artistic expression.

Nonetheless, to assume that Buddhism developed in China as an independent entity is to ignore the long, complex process of acculturation between Buddhism and indigenous elements. The feminization of the bodhisattva Avalokitesvara and the transformation of Maitreya...
Contemporary China and Taiwan

During the early twentieth century the monk Taixu (1889–1947) led a reform movement to organize the Buddhist clergy, promote social engagement and popular education, and propagate Buddhist studies among intellectuals. Under the leadership of Taixu a number of Buddhist institutes were established in the early 1920s, and the Chinese Buddhist Society was founded in 1929. The movement, however, was hindered by the War of Resistance against Japan (1937–1945) and the civil war between the Communists and the Chinese Nationalist Party (Guomindang) (1946–1949).

After the Communist victory in 1949 Buddhism suffered from official denunciation and periodic suppression. During the Cultural Revolution (1966–1976) Buddhist temples were closed, and monks and nuns were sent to work in fields and factories. After the Cultural Revolution, however, with the aid of government grants, Buddhist monasteries and nunneries have been restored, and the damaged Buddhist statues, images, and temples are being repaired. The government has also helped organize provincial and regional Buddhist associations. The Chinese Buddhist Association in Beijing, which was founded in 1953, has now resumed its national leadership. It sponsors the publication of Buddhist journals, establishes training centers for monks and nuns, and promotes Buddhist studies. The association is eager to extend its network to an international level, and it sends delegates to Buddhist conferences in south Asian countries, the United States, and Europe.

Whereas Buddhism suffered a serious blow under the Communists, it flourished in Taiwan, where the Nationalist government moved after its defeat in 1949. Between 1953 and 1986 the official representative of Buddhism was the Buddhist Association of the Republic of China (BAROC), led by a group of mainland Chinese monks who fled to Taiwan when Communists began to take over China. The association was authorized by Chiang Kai-shek’s Nationalist Party, and in turn it served the party’s interests. With the end of martial law in 1987, the BAROC lost its monopoly within Buddhist circles. Meanwhile, the government has increasingly granted autonomy to civic organizations, and, as a result, many Buddhist communities and organizations have risen to prominence. Most importantly, women play a significant part in all kinds of Buddhist activities. The lineage of bhiksunis (fully ordained nuns) in Taiwan has become the main source of legitimacy for Buddhist women who aspire to receive full ordination.

The two most prominent Buddhist organizations in Taiwan are the Ciji (Compassion Relief Foundation), founded in 1966 by the nun Zhengyan (b. 1937), and the Foguangshan (Mountain of Buddha’s Light) Monastic Order, founded in 1967 by the monk Xingyun (b. 1927). Ciji is the largest civic organization in Taiwan, currently claiming more than 5 million members worldwide. It has its own hospitals, medical school and university, journal, research center, and satellite television channel. Zhengyan started Ciji with one single goal: “To help the poor and educate the rich (jipin jiaofu).” By mobilizing lay volunteers, Ciji raises relief funds and enacts welfare reform. Recently the foundation has expanded its charitable work into the fields of bone marrow donation and environmental protection.

The Foguangshan Monastic Order likewise offers social services in addition to preaching the Buddhist teachings. It has a worldwide network of diversified operations, including temples, foundations, publications, libraries, charity services, and a satellite television channel. Xingyun particularly promotes the notion of “Humanistic Buddhism” or “Buddhism in the Human Domain” (renjian fojiao). The core ideal of Humanistic Buddhism is that salvation is achieved not in the other world but rather in the here and now and that all Buddhists should strive to build a Pure Land on Earth.

Both Ciji under the nun Zhengyan and Foguangshan under the monk Xingyun have demonstrated the capacity to adapt to a new age. Both are able to respond to the new political and economic situations in Taiwan, adopt modern technology to spread Buddhism, and modify old Buddhist teachings to meet the new religious needs of people. Under the influence of Zhengyan, Xingyun, and other Buddhist leaders, Buddhism in Taiwan has moved to a new stage of social engagement.

Although its emphasis on seated meditation is rooted in Indian Buddhism, Chan Buddhism is a genuinely Chinese product. The goal of Chan practice is to attain a sudden awakening of one’s inherent Buddha-nature. Chan texts are well known for their iconoclastic, non-conceptual style, characterized by a unique form of intuitive, spontaneous “encounter dialogues” between Chan Buddhists.

Chan is a Mahayana Buddhist school that developed in the Tang dynasty (618–907 CE) and flourished in the Song dynasty (960–1279). It emerged as a reaction against the intellectual tendency to conceptualize Buddhism. The word chan is from an abbreviation of channa, which is in turn a Chinese transliteration of the Sanskrit word dhyâna, meaning “meditation.” Aside from the Indian Buddhist emphasis on meditation, Chan also appropriates indigenous Daoist concepts such as naturalism, nondualism, and nonaction (wuwei).

History
Chan traces itself back to the historical Buddha (c. 566–486 BCE). According to the classical accounts of Chan lineage, during one of his sermons Śâkyamuni (the historical Buddha) made a wordless mind-to-mind transmission (ixin chuanxin) to his disciple Mahákâśyapa by saying nothing, but simply holding up a flower. The line of transmission was carried on through twenty-seven Indian patriarchs and eventually to Bodhidharma, who allegedly traveled to China around 520 CE and founded the Chan School. It is said that Bodhidharma meditated by facing the wall for nine years and that even his legs became withered.

Bodhidharma is acknowledged as the first patriarch of Chinese Chan Buddhism. From him the patriarchal lineage was transmitted to Huike (c. 485–574 CE), Sen-gzan (d. 606 CE), Daoxin (580–651 CE), and Hungren (601–674 CE). (These are not family names but “dharma names,” Buddhist names given to monks and nuns.) After Hungren the Chan lineage was split into two branches: the Northern School led by Shenxiu (605–706 CE), who is said to have taught gradual enlightenment (jianwu), and the Southern School led by Huineng (638–713 CE), who taught sudden enlightenment (dunwu). Shenxiu’s school eventually declined while the Southern School continued to grow. Huineng was later recognized as the legitimate sixth patriarch. His autobiography, sermons, and verbal exchanges with his disciples were included in the Platform Sûtra of the Sixth Patriarch (Liuzu Tanjing), dated around 780.

From Huineng the Chan lineage was expanded into the Five Houses and Seven Sects (wujia qizong). Among them the Linji School founded by Linji Yixuan (d. 866 CE) and the Caodong School by Caoshan Benji (840–901 CE) and Donshan Liangjia (807–869 CE) gained prominence in the Song dynasty. Both Linji and Caodong were introduced to Japan and Korea around the twelfth century and have continued to flourish there.
Doctrine and Practice

As a school of Mahayana Buddhism, Chan’s rationale for universal salvation is based on the doctrine of Tathāgata-garbha (rulai zang), embryo of the Buddha “Thus-come.” According to this doctrine, Buddha-nature as the absolute reality is the basis for human perfectibility. Every person is endowed with a Buddha-mind and can achieve enlightenment here and now. Enlightenment, as Chan claims, is to realize one’s innate Buddha-nature with sufficient faith.

The vision of Chan as a mind-to-mind transmission of the Buddha’s teaching is summarized in the following four-part slogan:

A special transmission outside the scriptural teachings (jiaowai biechuan);
Not setting up the written words (buli wenzi);
Directly pointing to the human mind (zhizhi renxin);
Seeing one’s self-nature and achieving Buddhahood (jianxing chengfo).

Although individual phrases appeared already in the Tang period, this conception of Chan’s self-identity did not emerge as a set formula until the early twelfth century and was attributed retrospectively to Bodhidharma.

The most common Chan practice is “sitting in meditation” (zuochan). In addition, Chan adopts the gong’an as an object of mental absorption. Gong’an, in origin a secular term for “public or legal case,” is a brief record that contains the unique form of intuitive, spontaneous “encounter dialogues” (jiyuan wenda) between Chan Buddhists. Mazu Daoyi (709–788 CE), for example, is well known in Chan history for his use of shouting, beating, and paradoxical statements to lead his students toward the experience of sudden enlightenment.

Under the Linji master Yuanwu Keqin (1063–1135) and his disciple Dahui Zonggao (1089–1163), Chan gong’an was no longer a literary piece intended for reading but rather an object used for meditation. Dahui, in particular, played a significant role in systematizing Chan gong’an meditation into the so-called kanhua Chan (Chan of investigating the [critical] phrase). The gong’an that Dahui often taught was the one attributed to Zhaozhou Congshen (778–897 CE):

A monk asked Zhaozhou: “Does a dog have Buddha-nature or not?”
The master said: “No (wu)!"

“No” is the huatou, “head of speech,” of this entire exchange. Dahui instructed students to simply meditate huatou and emphasized the peculiar role of doubt (yi) in kanhua Chan. He thus claimed, “A great doubt will definitely be followed by a great awakening.”

The Linji School was famous for its advocacy of gong’an meditation, while the Caodong School emphasized sitting in meditation, known as “Silent-illumination Chan” (mozhao chan). In practice, however, Chan masters would usually adopt both forms of meditation in teaching students in the monasteries.

Chan Buddhist Literature

A great number of Chan texts were written and compiled during the Song dynasty. The main characteristic of Chan literature is the unique form of “encounter dialogues.” There are altogether three distinctive Chan genres: (1) the “discourse records” (yulu) that focus on the words and deeds of a single Chan master; (2) the “lamp histories” (denglu) that chronologically list the biographical accounts of a series of Chan masters in various lineages of transmission; and (3) the gong’an anthologies, among which the Record of the Blue Cliff (Biyen lu) by Yuanwu Keqin and the Gateless Gate (Wumen guan) by Wumen Huikai (1183–1260) are perhaps the most well-known works.

Chan and Chinese Literati Culture

Chan Buddhism had a close connection with Chinese literati culture. The sudden/gradual polarity that characterized the development of Chan became a dominant theme in Chinese poetic criticism, painting theories, and intellectual discourse. Literary critics and poets frequently discussed poetry in terms of Chan’s notion of the relationship between practice and enlightenment. Theorists of painting liked to analyze artistic expression...
by analogy to the Northern and Southern schools. The Chan concept of lineage transmission was influential in Song neo-Confucians’ formation of the “Orthodox Succession of the Dao” (daotong), and the Chan doctrine of Buddha-nature also played a crucial role in the neo-Confucian advocacy of “Learning of the Mind” (xinxue).

**Chan Today**

In modern China notable monks such as Taixu (1890–1947) and Yinshun (1906–2005) studied Chan. Xuyun (1840–1959) was a renowned Linji master, and Shengyan (b. 1930) received the dharma (basic principles of cosmic or individual existence) transmission in both the Linji and Caodong lineages. Chan meditation is a common practice among Chinese Buddhists today. Since the 1960s Chan has also attracted a large number of people in the West. Known commonly in the West as “zen” for its Japanese pronunciation, Chan becomes a fashion of spiritual pursuit and a source of inspiration for artistic expression.

Buddhism, Four Sacred Sites of

The four sacred sites of Buddhism in China are Wutai Shan, Emei Shan, Jiuhua Shan, and Putuoshan, mountain homes of Buddhist enlightened ones. Although the religious complexes at these sites are smaller than those existing at the height of Buddhism’s existence in China, the “holy mountains” remain attractions for their religious context and artifacts and for their natural beauty.

The “four most famous Buddhist mountains” (sida Fojiao mingshan) were traditionally considered as bodhimanda (mountain residences) of bodhisattvas (pusa in Chinese), spiritual beings who, according to Buddhist scriptures, assist all sentient beings in transcending suffering. The Chinese tradition of “paying respect to a holy mountain” through pilgrimage (chaobai sheng shan) predates the arrival of Buddhism in China. This pilgrim tradition was mentioned in the Shujing (fifth century BCE compilation of documents relating to ancient Chinese history), and it was probably related to the ancient cosmology according to which mountains provided access to the heaven, served as pillars for the sky, or constituted abodes where Daoist sages, shamans, and immortals lived. Buddhist monks hoped to visit the four mountains; there was a widespread belief among them that the bodhisattva of each mountain would take the form of an individual and show itself to pilgrims, sometimes in the form of another monk, sometimes as a beggar. Pilgrims traveled long journeys, from their points of departure to one of the mountains, by making a prostration—touching the ground with the head every three steps. It was customary for pilgrims to visit in this way all the temples and shrines in the mountains. Lay Buddhists visited these mountains in great numbers to make vows (huanyuan) or to perform penance. Many nonbelievers also traveled to the sacred sites to accomplish a feat from which they could derive prestige. The pilgrimages were often in groups because the journey to the nearest cities to the sites was sometimes long and dangerous.

Wutai Shan: Five Terraces Mountain

Wutai Shan, or the “five terraces mountain,” in Shanxi Province, is the bodhimanda for Wenshu Pusa (the bodhisattva of Wisdom; in Sanskrit, Manjusri, “Gentle Glory”). It is often referred to as the “first of the four sacred Buddhist mountains” because it was the first to be identified as sacred. Temples were built during the rule of Emperor Ming Di (reigned 58–75 CE), and by the time of the Qi dynasty (550–577 CE) up to two hundred existed, but most were destroyed later. Today over fifty-eight temples remain, including the oldest wooden structures of China, the Nanchan Monastery and the East Hall of Foguang Monastery, built in 782 and 857, respectively.

Because it has long been difficult to access, Wutai Shan was spared much of the destruction of the Cultural Revolution (1966–1976). Currently, better roads have facilitated access to the site, and it has become a major
tourist destination. Tradition claims that Wenshu can offer pilgrims extraordinary visionary experiences, and the site is also considered a location of importance for Daoists. The Chinese government hopes that Wutai Shan will be added to the United Nations Educational, Scientific, and Cultural Organization (UNESCO) list of World Heritage Sites. Yedou Shan, the highest of the five peaks, has an elevation of 3,061 meters.

Emei Shan: Towering Eyebrow Mountain

Emei Shan, or the “towering eyebrow mountain,” in Sichuan Province, is the bodhimanda for Puxan Pusa (the bodhisattva of Benevolent Action; in Sanskrit, Samantabhadra, the “Universal Worthy”). Many consider Sichuan to be the first location in China where Buddhism was practiced, and claim that it is in this area that the first Buddhist temple was built in the first century CE. By the fourteenth century, the site had over one hundred temples, monasteries, and other buildings. Seventy of these remain today, but only twenty are active.

Because of the wet climate, the summit is often foggy. Under certain meteorological conditions, refraction of water particles produces rainbow rings that surround one’s shadow over a sea of clouds below the summit. Known as “Buddha’s light,” this phenomenon has inspired devotees to jump off the cliff convinced that this was a sign from heaven calling them, which prompted the authorities to set up barriers to prevent suicides. Emei Shan’s scenic area, which includes the carved stone Buddha of Leshan,
was made a UNESCO World Heritage Site in 1996. At 71 meters high, the sitting Buddha statue is the tallest of its kind in the world, and with an elevation of 3,096 meters, Emei Shan is the highest of the four sacred mountains.

**Jiuhua Shan: Nine Glorious Mountains**

Jiuhua Shan, or the “nine glorious mountains,” in Anhui Province, is the bodhimanda for Dizang Pusa (the bodhisattva of Salvation; in Sanskrit, Ksitigarbha, the “Earth Treasury”). This bodhisattva, who has vowed to delay the attainment of Buddhahood until all beings are freed from hell, is much revered in East Asia.

In 719 CE, a wandering Korean Buddhist, Kim Xiao Kak, came to his journey’s end and founded a temple dedicated to Dizang Pusa. After Kim’s death, the site’s eminence rose. During the Tang dynasty (618–907 CE), there were about 150 temples and thousands of monks in residence. By the Ming dynasty (1368–1644) and the Qing dynasty (1644–1912), there were as many as 360 temples and between four thousand and five thousand monks and nuns. But as a consequence of the destruction caused by political and social upheavals from 1851 until 1976, the site now counts only seventy temples and monasteries.

The tradition claims that the area received its name after the poet Li Bai wrote that its nine mountains were holding heaven. The area is difficult to access, but this relative isolation makes it more peaceful than the other great tourist site in Anhui Province, Huangshan (Yellow Mountain). The highest of the peaks in the area is 1,342 meters high.

**Putuoshan: Mountain of the “One who Perceives Sounds”**

Putuoshan, on the island of Zhoushan in Zhejiang Province, derives its name from Potalaka, the bodhimanda of Guan Yin (the “One who Perceives Sounds”) Pusa, the Chinese version of the bodhisattva of Compassion (in Sanskrit, Avalokitesvara, the “Lord who looks down”). A feminine figure, Guan Yin is a revered bodhisattva throughout East Asia.

Putuoshan became a site for Buddhist pilgrims slightly later than the other mountains. In 916, the island became the primary shrine to Guan Yin, and during its heyday, it counted over eighty temples and nunneries, as well as over 120 shelters that could house over four thousand monks and nuns. Today, there are five hundred resident monks on the island. This is noteworthy in the history of contemporary Buddhism because it was chosen as a retreat by the famous reformist monk Taixu.

Much closer to the wealthy and densely populated parts of China, Zhoushan is easy to access, and therefore it is a popular tourist destination. Foding Shan, the highest peak on the island, rises 297 meters.

The four sacred mountains of Buddhism, each dedicated to a different Buddhist holy being, remain pilgrimage and tourist destinations today.

Buddhism, introduced from India, became widely accepted in China in the third century CE but suffered from persecution over the years for various reasons: rejection of Buddhism as a foreign or idolatrous religion, feelings of antireligion in general, or by the desire to redistribute the wealth and land owned by Buddhist temples.

Although Buddhism did not come to China through violent military conquest, its introduction was not easy, and it took centuries before Buddhism was widely accepted. The religion was widely embraced only after the fall of the Eastern Han dynasty (25–220 CE), and was adopted by the rulers of smaller kingdoms. This embrace, however, was not universal, and the religion suffered from persecution. Chinese sources mention the “three disasters of Wu,” from the names of the emperors under whom bans against Buddhism were enforced. Persecutions have also occurred in the late dynastic era, during the Republican period, and in the People’s Republic of China.

### The First Disaster of Wu

The first disaster occurred in 446 CE, when northern China was under the control of the Toba (or Xianbei) people, during the Northern Wei dynasty (386–534 CE). The Emperor Taiwu (reigned 423–452 CE) prohibited Buddhism, following the urging of his Prime Minister Cui Hao. Cui, who wanted to establish an ideal Confucian state in North China, considered Buddhism to be a foreign religion that had to be eliminated in order to sinicize the Toba people. Decrees designed to weaken the monastic organization were issued beginning in 438 CE; in 444 CE, one decree proclaimed that the penalty for privately supporting monks was death. In 446 CE, believing monks were helping his enemies and finding weapons in temples, Taiwu prohibited the religion throughout the empire. He ordered the slaughter of monks, the destruction of temples, and the burning of sutras (classic Buddhist religious texts). This ban, however, did not affect Buddhists in southern China, ruled by the Liu Song (420–479 CE). The ban in North China was short-lived. The crown prince Huang, himself a devout Buddhist, helped monks to escape or hide, and the ban was formally ended in 452 CE, after Taiwu was assassinated and his grandson Wencheng (reigned 452–465 CE) acceded to the throne.

### The Second Disaster of Wu

The second disaster occurred during a period when China was still divided, this time between the two short-lived dynasties of the North and South Dynasties period, Northern Zhou (557–581 CE) and the Chen (557–589 CE) to the south. This second wave of persecutions was carried out by the Zhou Emperor Wu (reigned 560–578 CE) in 574. The Zhou ruling house was not of Chinese origin, and the Emperor sought to demonstrate that he was Chinese
in his thinking and action. He was initially reluctant to voice his displeasure over Buddhism because of its influence over many of his subjects. He was encouraged to denounce the religion, however, by a memorial written to him in 567 CE by Wei Yuansong. Wei argued that the religion was wasteful and that it impoverished the country, but that because its main virtue was its teaching of compassion, it should be managed by the state, and the clergy returned to lay life. The Emperor Wu was infuriated by protests from the monks in 574 CE and decreed the suppression of the religion. After his conquest of the Northern Qi in 577 CE, Wu issued another decree extending the proscription over the rest of North China. This persecution, however, was also short-lived and limited in its effects: it stopped after the Emperor Wu’s death in 578 CE. In 581 CE, the Northern Zhou were superseded by the Sui, who proclaimed Buddhism as state religion.

Under the Sui (581–618 CE) and the Tang (618–907 CE) dynasties, Buddhism experienced great prosperity and influence. The memorial of Fu Yi against Buddhism, written in 621 CE, was one of the most important documents written against the religion, but it is a testimony to the status Buddhism enjoyed that for more two centuries no persecution affected the religion. In fact, Buddhism benefited from state patronage under the first decades of the Tang dynasty, most remarkably under the Empress Wu Zetian (reigned 690–705 CE). The state patronage of Buddhism under the Empress, however, represented a turning point. After her rule, Emperor Xuanzong (reigned 712–756 CE) adopted a series of measures to regulate Buddhism, and put the religion on an equal footing with Daoism. The large amount of Buddhist land exempt from taxation and the vast wealth in temples that was unavailable to the state continued to stir objections from Confucian and Daoist men of letters.

**The Third Disaster of Wu**

The factional strife within the court contributed to the third disaster of Wu. The emperor and scholar-bureaucrats opposed the privileges of the Buddhist religion and the eunuchs approved it; ideological conflicts occurred between Daoism, which was portrayed as a genuine Chinese religion, and Buddhism, which was criticized as foreign; and finally, a great loss of revenue to the state was caused by the exemption granted to temples. This unfolded from 842 to 845 CE, when Tang Emperor Wuzong ordered that Buddhist temples, shrines, and statues be destroyed and that their landed properties be confiscated, forcing the secularization of the clergy. Like the previous two persecutions, it started out as a violent and sudden attack, but it was quickly terminated, this time with the death of Wuzong. This last suppression of Buddhism was much larger in its scope than the two previous ones: it unfolded throughout the empire, and its consequences for the religion were long lasting. Buddhism never recovered fully from this persecution. This last wave of persecution also differed from the previous two persecutions and from the anti-Christian persecutions in ancient Rome and the
persecution of Buddhism, which 235

religious wars that would divide Europe seven centuries later: Buddhists were not killed because of their beliefs, and monks were simply returned to lay life.

**Persecution in the Nineteenth and Twentieth Centuries**

Arguably, three other waves of persecution could be added to this list. The first one, under the Qing dynasty (1644–1912), resulted from the Taiping uprising of 1851–1864. This persecution against Buddhism was not caused by the government, the weak Emperor Xianfeng (reigned 1851–1861), or his successor Tongzhi (reigned 1862–1874), who was a child when he succeeded to the throne. The Taiping Rebellion, motivated by a utopian ideal of land distribution and a messianic belief that borrowed loosely from Christianity, sought to destroy Buddhist and Daoist temples, which were viewed as symbols of idolatry. The leader of the Taiping, Hong Xiuquan, believed he was the younger brother of Jesus and resolved to fight evil in this world to establish a Heavenly Kingdom of Great Peace (Taiping Tianguo). He also believed that the Buddhist and Daoist religions were part of the evil on earth, and many temples were destroyed wherever his troops were in control. Only after the rebellion was quelled by the Qing dynasty could Buddhists rebuild their temples.

The second persecution, under the Republican regime (1912–1949), occurred as part of a short-lived antireligionist movement that sought to convert temples into schools between 1923 and 1927. In this period of great political instability and division, many members of the Nationalist Party’s radical wings who sought to modernize China encouraged the transformation of temples into schools. This time the Buddhist clergy and lay people did react. They mobilized and pressed President Jiang Jieshi to stop the campaign. The generalissimo, who also wanted to limit the influence of the radical elements in the Nationalist Party, put an end to that wave of temple expropriation.

Finally, the third persecution of modern times broke out during the Cultural Revolution (1966–1976). These persecutions were not limited to Buddhists and were antitraditionalist as well as broadly antireligious. During these ten years of disorder monks and nuns had to return to lay life, and some were forced to participate in public self-criticism sessions. Temple properties were sacked and destroyed by the Red Guard, or closed and converted to other use. For example, the Jing’an temple in Shanghai, which was originally built in 246 CE, became a plastic factory during the Cultural Revolution and was reopened only in 1983.

The Chinese government since the beginning of reform has adopted a very different attitude toward Buddhism. It recognizes its value as part of the national cultural heritage and as a resource to help diplomatic relations with many neighboring Asian countries where Buddhism is an important religion. In recent years, the government has encouraged the restoration of temples, the development of pilgrimages, the development of Buddhist associations engaged in publishing and philanthropic activities, and even the organization of major international symposia on Buddhism. Buddhist associations themselves have been eager to show that they support the government by supporting its campaign against “evil cults,” taking charge of orphanages and schools for disabled children, and organizing relief during national disasters such as the 2008 earthquake in Sichuan. The official statistics remain vague but there is agreement that Buddhism is experiencing a revival of its fortune among ethnic Chinese.

Another development of note is the popularity of Tibetan Buddhism among non-Tibetans. However, the Communist Party remains hostile to the idea that the Dalai Lama represents the religious authority for Tibetan Buddhists, despite the anecdotal evidence that shows this is the wish of a majority of Tibetans.

In sum, although diminished politically and culturally as an institution, Buddhism nevertheless survives in China to this day, albeit as a shadow of its former self.

Buddhism, Pure Land

Jingtǔ 淨土

Pure Land Buddhism teaches that faith in the power and grace of Amitabha Buddha, who presides over the western Pure Land, will lead to final salvation. This originally Indian Mahayana form of Buddhism has not only been transformed into a uniquely Chinese Buddhist school but has also become one of the most popular religions in East Asia.

Pure Land Buddhism is based on three principal scriptures written originally in Sanskrit. The Shorter Pure Land Scripture (Sukhāvatīvyūha-sūtra; Chinese: Amito jing) tells the story of Amitâbha and depicts the wondrous qualities of his paradise. The Longer Pure Land Scripture (Chinese: Wuliangshou jing) is an expansion of the shorter one. Finally, the Scripture of Meditation on the Buddha of Measureless Life (Amitâyurdhyāna-sūtra; Chinese: Guan wuliangshou jing) contains thirteen practices of visualization on Amitâbha and his Pure Land.

The Longer Pure Land Scripture was translated first into Chinese by Samghavarman around 252 CE. However, the Shorter Pure Land Scripture, translated by Kumârajīva (344–413 CE) in 402, gained wide popularity among Pure Land devotees. The Scripture of Meditation on the Buddha of Measureless Life is said to have been introduced to China by Kâlaya'sas around the first half of the fifth century, but many scholars speculate that it is actually an apocryphal text composed in China or central Asia.

Doctrine and Practice

According to the Pure Land teaching, this world is full of suffering and defilements, and people alone can hardly save themselves. Salvation, therefore, is achieved best at another time (in the next rebirth), in another place (the Pure Land), and through another power (that of Amitâbha). One of the theories developing in Pure Land Buddhism, furthermore, is the coming of the “Age of the Final Dharma” (mofa). It is believed that after the age of the “Orthodox Dharma” (zhengfa) and then the age of
the “Semblance of the Dharma” (xiangfa), Buddhism will enter its final stage, during which people are no longer capable of achieving enlightenment, and all the traditional Buddhist practices are impossible to carry through. The only path to nirvana is via rebirth in the Pure Land by having faith in the power and grace of Amitâbha Buddha.

Pure Land scriptures thus contain a variety of practices to help people cultivate their faith in Amitâbha and his Pure Land. In China mindfully reciting Amitâbha’s name, known as nianfo in Chinese, has been the most popular practice; daily repetition of the simple phrase “Homage to Amitâbha Buddha” (Nanwu Amito Fo), often counted with the beads in a rosary, is believed to ensure the devotee’s rebirth in the Pure Land.

Faith in the reward of paradise usually coexists with the fear of punishment in hells. In Pure Land painting and writing the joys and blessings of the Pure Land are often shown in sharp contrast to the horrors and miseries of hells. Fearing to be reborn in hells, people will become even more motivated to do meritorious deeds and cultivate the Pure Land faith.

Devotion to the bodhisattva Avalokite’svara, the chief assistant of Amitâbha, is also popular. Originally an Indian male deity, Avalokite’svara is transformed into a goddess of great mercy and compassion, called “Guanyin” or “Guanshiyin” in Chinese. Belief in her efficacy and miraculous aid in times of need makes Guanyin a widespread religious cult throughout China.

Pure Land Patriarchs and Masters

In China, Pure Land Buddhism never developed into a distinctive, full-fledged sect (zong); its transmission lineage was actually established through the monks of Tiantai, another Chinese Buddhist school, in the Southern Song dynasty (1127–1279). Throughout most of Chinese history Pure Land teachings and practices were mingled with or incorporated into other forms of Buddhism.

Nonetheless, many monks were known for their influential roles in popularizing Pure Land devotion. The first Chinese Pure Land center was the White Lotus Society founded by the monk Huiyuan (334–416 CE) on Mount Lu (present-day Jiangxi) in 402 CE. Huiyuan was later regarded as the founder and first patriarch of Chinese Pure Land Buddhism. After Huiyuan, a series of masters contributed further to systematizing the Pure Land doctrine and popularizing the practice.

Tanluan (476–542 CE) began to advocate nianfo among lay people. Daochuo (562–645 CE) wrote the Collection of Essays on [the Land of] Peace and Happiness (Anle ji) to emphasize the point that to be free from suffering and defilement, all one needs to do is have faith in Amitâbha. His disciple Shandao 善導 (613–681 CE) laid out the definite framework for Chinese Pure Land Buddhism. In his influential Commentary on the Scripture of
Meditation on the Buddha of Measureless Life (Guanjing su), moreover, Shandao made a significant shift of emphasis from the practice of visualization on Amitâbha to the devotion through nianfo, insisting that the latter was not only the right practice but also the most efficient one to ensure a rebirth in the Pure Land.

After Shandao the two important Pure Land masters who sought to synthesize Chan (Japanese: zen) and Pure Land were Cimin Huiri (680–748 CE) and his disciple Fazhao (c. 800 CE). In later times continued efforts were made to align the Pure Land nianfo with Chan gong’an meditation. The question “Who is the one reciting Amitâbha’s name?” becomes a gong’an for people to contemplate in their meditation.

Pure Land Buddhism has also enjoyed a wide appeal in Japan. Monk Hônen (1133–1212) founded the Jõdo shû sect, while his disciple Shinran (1173–1262) founded the Jõdo Shinshû sect. Both sects remain active today.

Amitâbha’s western paradise really exists, he encouraged his followers to practice nianfo on a daily basis. His lay disciple Li Bingnan (1890–1986), who moved to Taiwan in 1948 when the Communists began to take over China, continued to promote Pure Land Buddhism. Monk Xingyun (b. 1937), founder of the Fouganshan monastic organization, urges people to make Taiwan a Pure Land in this world. On the whole, Amitâbha worship and the belief in the Pure Land have always been popular among Chinese Buddhists.

Buddhism, Tibetan
Zàng Chuán Fójiào 藏傳佛教

Tibetan Buddhism is one of most important and rigorous living Buddhist traditions in the world. Its history can be traced back to the seventh century. Tibetan Buddhists have also developed their unique monastic rituals and scholastic tradition.

Although Tibetan Buddhism is known by many unofficial terms in numerous popular books, including Vajrayana (Vehicle of the Diamantine Thunderbolt), Tantrayana (Vehicle of Tantra), and Lamaism (Teaching of Spiritual Master), by consensus it is a Mahāyāna Buddhist tradition that pursues Budhhahood, the highest state of enlightenment. In many other Mahāyāna Buddhist traditions in central China, Korea, and Japan, Tibetan Buddhism is also considered a special branch of Esoteric Buddhism, which is different from the Esoteric Buddhism of other regions, such as Han Esoteric Buddhism in central China and Shingon Buddhism in Japan. It is noteworthy that Esoteric Buddhism is neither the only religious tradition in Tibet nor the exclusive religion among Tibetans. However, in Tibet the esoteric tradition is regarded as the highest form of Buddhism. Before Buddhism was introduced to Tibet in the seventh century, the Tibetans were adherents of the Bon religion. Later Chan Buddhism, Manichaeism, and Nestorianism briefly flourished in Tibet from the eighth to the tenth centuries.

The first important figure in the history of Tibetan Buddhism was the Emperor Srong-btsan Sgam-po (605–650 CE). Tibet first became a unified empire and began to expand under his reign. He began to establish a firm friendship with Tibet’s neighbors, the kingdom of Nepal and the Tang dynasty, by marrying the Nepalese princess Khris b’Tsun and the Chinese princess Wencheng (Tibetan: Mung-chang Kungco), the daughter of the Tang emperor Taizong. The princesses, both Buddhists, brought their religion to Tibet. Thereafter, Srong-btsan Sgam-po initiated the construction of Buddhist temples. Srong-btsan Sgam-po was viewed as the first Dharma-Raja, the righteous ruler who supported and advocated the Buddha’s teaching. Later kings were less interested in advocating Buddhism. However, when Khris-srong Lde-btsan came into power in the eighth century, he invited some influential Indian masters such as Shantarakshita and Padmasambhava to teach in Tibet. With his efforts Buddhism revived and flourished, taking shape as a new tradition during his era. Since the late eighth century the Tibetan ruler has been viewed as the embodiment of the bodhisattva (a being that compassionately refrains from entering nirvana in order to save others and is worshipped as a deity in Mahāyāna Buddhism) Avalokiteshvara, known in Chinese as “Guanyin.”

In the ninth century the Tibetan empire conquered many regions in central Asia and even temporarily blocked the silk trading route that linked central China and central Asia. Tibetan Buddhism was also spread to some oasis towns on the Silk Roads, such as Turfan and Dunhuang. Numerous manuscripts written in Tibetan have been discovered in Dunhuang. Starting in the eleventh century, Tibetan Buddhism gradually spread to the nomadic tribes who ranged through the Mongolian area. Subsequently
Tibetan Buddhism was accepted by the Mongols and Manchurians and even became the state religion of the Chinese Yuan (1279–1368) and Qing (1644–1912) dynasties. In 1578 an abbot at the Drepung monastery, Sonam Gyatso, received the title of “Dalai Lama,” which later became the official title of the head of the Tibetan Buddhist Church. “Dalai” means “the ocean” in Mongolian, which refers to the Tibetan word “Gyatso.” Lama is from the Sanskrit word “Guru,” the spiritual teacher. Sonam Gyatso was viewed as the third Dalai Lama. The current Dalai Lama, Tenzin Gyatso (b. 1935), is the fourteenth leader who holds the title of Dalai Lama. The traditional seat for the Dalai Lama is Potala Palace in Lhasa, the capital of Tibet. The second-ranking official in the Tibetan Buddhist Church is the Panchen Lama, whose traditional seat is at Tashilhunpo Monastery in Shigatse. The tenth Panchen Lama was Lobsang Trinley Lhündrub Chökyi Gyaltsen (1938–1989), commonly known as Chökyi Gyaltsen. Since the twentieth century Tibetan Buddhism has also spread to other neighboring regions besides Qinghai, Mongolia, and Manchuria, notably Nepal, Bhutan, and western Sichuan and Yunnan provinces in China. After the 1960s, with the exile of the Tibetan government, Tibetan Buddhism also spread to Europe and North America. Nowadays there are numerous Tibetan Buddhist centers in the United States.

**Doctrine and Practice**

The textual foundation for Tibetan Buddhism is the Tibetan Buddhist canon, which is usually divided into two categories: Kanjur and Tanjur. The former includes sections of the Vinaya Perfection of Wisdom sutras (discourses of the Buddha that constitute the basic text of Buddhist scripture), Avatamsaka, Ratnakuta, and other Mahāyāna and Agāma sutras, as well as tantras (later Buddhist scriptures dealing especially with techniques
The latter includes commentaries and treatises. The esoteric tradition of Tibetan Buddhism is a Mahāyāna tradition, mainly based on the Madhyamika theory of the “Middle Way” (dbu-ma). In general it teaches fast and complete enlightenment; yet, certain esoteric aspects make it unique in terms of tantrism, which emphasizes the application of divine power and the guidance of the spiritual gurus. Other important practices include the use of mantra (enlightened sound, powerful syllables), mandala, and sexual rituals involving female participation. In order to pursue Buddhahood, Tibetan Buddhism develops a unique method for a practitioner to control his or her body, speech, and mind as three esoteric elements. This method is designed to help practitioners eliminate negative karma (the force generated by a person’s actions held in Buddhism to perpetuate transmigration and in its ethical consequences to determine the nature of the person’s next existence). It requires its practitioners to develop strong contemplative powers through meditation and visualization. Unlike in other Buddhist misogynic traditions, the female plays an important role as a companion in the practice of Tibetan Buddhism. Tibetan Buddhism has inherited some aspects of the indigenous Bon religion: For instance, it relies on the supernatural power of shamans. The famous mantra Om mani padme hum is said to be able to invoke powerful blessing.

The term mandala literally means “circle” and refers to a pattern that represents a cosmos or a microcosmos of both mental and spiritual dimensions. The Tibetan mandala usually consists of an inner square and an external circle, often occupied by the divine figures, such as Buddhas and bodhisattvas. It functions as a sacred place where the deities manifest themselves in what is known as the “Buddha field.” In Tibetan Buddhism the mandala is a crucial visualization technique used in meditation. It also plays a central role in the rituals of purification and visualization. Sand mandalas are also often constructed and immediately destroyed in the teaching of Tibetan Buddhism; this process symbolizes the critical Buddhist concept of impermanence.

**Schools of Tibetan Buddhism**

Tibetan Buddhism has four main traditions: Nyingmapa (also known as hong jiao in Chinese or “red school”), Kagyupa (bai jiao in Chinese or “white school”), Sakyapa (hua jiao in Chinese or “flower school”), and Gelugpa (huang jiao in Chinese or “yellow school”).
Nyingmapa is also called the “ancient ones,” denoting the oldest school that was founded by Padmasambhava. It focuses on meditation practice. Numerous meditation centers are affiliated with this school. Kagyupa is the school of “oral lineage,” which emphasizes the transmission of teaching and practice from the master to the disciple. Sakyapa literally means “gray earth” and originated in the Sakya Monastery following its construction in 1073. Gelugpa means “way of virtue” and was founded by Gyalwa Tsongkhapa (1357–1419). Since its later origin it has comprehensively incorporated many ideas and practices of the first three schools as well as traditional Mahāyāna teachings. It is commonly called the “Yellow Hat School,” whereas the former three schools are called “Red Hat schools.” The current Dalai Lama belongs to the Gelugpa lineage. In Tibetan Buddhism, the incarnated lamas also earn a title commonly known as Rinpoche, which literally means “the precious one.” Tibetan Buddhism, especially the Gelugpa tradition, emphasizes scholastic learning. Tibetan Buddhist scholastic tradition develops a series of titles for different degree holders. The highest degree is called Geshe, which means “spiritual friend” in Tibetan. The curriculum of Geshe study is involved in the learning of Scriptures, commentaries, treatises, and monastic code.

The currently Beijing-based Buddhist Association of China (BAC) was founded in Shanghai in 1927 by lay Buddhists who were inspired by reformist monks such as Taixu to defend their collective interests. The organization fell apart during the civil war and its factions split under Communist rule, but resumed activities in 1976 under the leadership of Zhao Puchu.

Until recently only two organizations claimed to represent all Buddhists in China: the Buddhist Association of China ([BAC] zhongguo fojiao xiehui), based in Beijing, and the Buddhist Association of the Republic of China ([BAROC] zhongguo fojiaohui), based in Taipei, Taiwan. This situation differs from that in imperial China, when Buddhists were not affiliated with a unique institution. In the absence of a supreme authority Buddhists have been spared internecine (occurring within a group) conflicts over doctrine, but on the other hand they have been vulnerable to attempts by the state to control or even suppress their activities.

Beginning with the persecution against them during the Tang dynasty (618–907 CE), Buddhist institutions experienced a secular decline until laypeople revived the tradition through charity work at the end of the nineteenth century. Although the Qing dynasty (1644–1912) was supportive of the Tibetan Buddhism practiced by Mongols, Tibetans, and other minorities, it did not protect

Fei lai feng Buddha, from the Yuan dynasty (1279–1368). Photo by Joan Lebold Cohen

Buddhist institutions during the Taiping Rebellion, and the later emperors were too weak to react when modernizers converted temples into schools. In this context lay Buddhists during the beginning of the Republican period
(1912–1949) tried to set up a unified Buddhist organization to defend their collective interests. In 1927, inspired by reformist monks such as Taixu (1890–1947), they founded the BAC in Shanghai. The civil war proved fatal to the organization, which split after the Chinese Communist Party (CCP) took power. Some monks went into exile in Hong Kong, others to Taiwan or abroad. In 1950 exiled monks living in Taiwan created the BAROC, which exercised a monopoly of representation for all Buddhists on the island and claimed to represent all Chinese Buddhists in international Buddhist organizations during the period of martial law (1947–1987).

Although the BAROC represented a small proportion of Chinese Buddhists in the world, it was the only organization recognized by the World Buddhist Sangha Council. The BAROC benefited from the protection of the government, but its authority declined at the onset of the democratization process as new organizations, such as the Fuguangshan monastic order and the Tzu Chi Foundation, became much more important in Taiwan and within the Chinese Diaspora (scattering of a people). Meanwhile, in the People’s Republic of China, the CCP encouraged monks and laypeople to join the BAC, which was reconstituted in 1953. The BAC was cautious and expressed its loyalty to Chinese authority, but this attitude did not prevent the organization from suffering persecution during the Cultural Revolution (1966–1976). As a result the organization could not operate for years, and its future was uncertain. The BAC finally resumed activities in 1976 under the leadership of Zhao Puchu (1908–2000), a lay leader who shared the ideas of Taixu. Under his leadership Buddhism experienced a remarkable comeback and even an endorsement by CCP leader Jiang Zemin. In 2006 the BAC sponsored a historical gathering in Hangzhou, China, when it organized the first World Buddhist Forum, at which monks from the People’s Republic of China, Hong Kong, and Taiwan jointly acted as overseers.

Since 1954 the Bureau of Religious Affairs has been responsible for protecting freedom of religious belief. Although the bureau has been instrumental in helping religious bodies restore properties lost or destroyed during the Cultural Revolution (1966–1976), it has also monitored so-called ethnic, politically suspect, or unregistered religious groups whose activities are perceived to be at odds with the maintenance of national unity.

Established in 1954, the Chinese national government’s Bureau of Religious Affairs protects freedom of religious belief and fosters the rule of law and patriotism by linking legitimate religious activities with the maintenance of state order, national unity, and socialist development. Administered by the State Council, the bureau’s tasks are to register venues (such as monasteries and churches) for “normal religious activities,” to ensure that religious organizations are not subject to any foreign domination, and to protect freedom of religious belief.

Article 36 of the 1982 Chinese constitution defines “normal religious activities” as activities that do not “disrupt public order, impair the health of citizens, or interfere with the educational system of the state.” This definition reflects the post-1976 shift away from the fiercely antireligious stance of Chinese Communist Party leader Mao Zedong (1893–1976), but it also echoes Chinese state policies toward religion established as early as the Han dynasty (206 BCE–220 CE).

The People’s Republic of China claims that the bureau fosters the rule of law and patriotism by linking legitimate religious activities with the maintenance of state order, national unity, and socialist development. The bureau has been instrumental in helping religious bodies reclaim and restore properties lost or destroyed during the Cultural Revolution (1966–1976). It also has tended to scrutinize some religious groups and activities more than others, especially so-called ethnic religions (Buddhism in Tibet and Inner Mongolia, Islam in Xinjiang Uyghur Autonomous Region), small unregistered bodies (charismatic Protestant Christian house churches), “superstitions” (mixin) such as fortune-telling and faith healing, and politically suspect groups (Falun Gong/Falun Dafa). Recently the bureau has gone beyond regulation to assert the right of the Chinese state to adjudicate the status of anyone claiming to be a reincarnated Buddhist figure, such as the Dalai Lama of Tibet, and has proclaimed that no one born outside of China’s borders will be so recognized.

Bureau of Religious Affairs Upholds the Constitution

The Constitution of the PRC represents a formal articulation of Party policy. As Peng Zhen, then Vice-Chair of the Committee to Revise the Constitution, pointed out in 1980, “The party leads the people in enacting the law and leads the people in observing the law.” This edict remains a bulwark of the Party’s approach to law making. During the post-Mao period, policies of limited tolerance for religion were reflected in the provisions of Article 36 of the 1982 Constitution.

- Citizens of the People’s Republic of China enjoy freedom of religious belief.
- No state organ, public organization or individual may compel citizens to believe in, or not to believe in, any religion: nor may they discriminate against citizens who believe it, or do not believe in any religion.
- The state protects normal religious activities. No one may make use of religion to engage in activities that disrupt public order, impair the health of citizens or interfere with the educational system of the state.
- Religious bodies and religious affairs are not subject to any foreign domination.

As an American diplomat in China in the 1860s, Anson Burlingame advocated expanding commerce and promoting Christian missionary efforts. After retiring from public service he became an advisor to the Qing court. With the Burlingame-Seward Treaty of 1868, he helped forge one of the least-humiliating agreements, which in part welcomed Chinese immigrant labor to the United States, in China’s unequal treaty era.

Anson Burlingame shaped relations between the Qing dynasty (1644–1912) court and the United States in the 1860s. His career in China grew from political failure in the United States. Burlingame lost an election for the House of Representatives in 1860 and was to have been U.S. minister to Austria but the county refused to receive him as minister. President Abraham Lincoln then appointed him envoy extraordinary and minister plenipotentiary to China in June 1861. During the U.S. Civil War the Lincoln administration focused on preventing European powers from recognizing the Confederacy, and China was not a priority. Nor was the United States important to the Chinese, who were confronting domestic upheaval in the Taiping Rebellion and external threats from the British and French.

While never abandoning the goals of expanding commerce and promoting Christian missionary efforts, Burlingame did urge Europe and the United States to limit their demands on China. He retired from government service in 1867 and was immediately employed by the Qing dynasty as an advisor and envoy. Hiring foreigners to assist in relations with foreigners was not unprecedented. For example, Jesuit missionaries negotiated the 1689 Treaty of Nerchinsk with Russia on the Qing dynasty’s behalf. The Qing court and prominent officials such as Li Hongzhang sought to reduce Western imperialism by highlighting China’s development and ability to cooperate with the outside world. In 1868 Burlingame...
was accompanied by two Chinese envoys to the United States and Europe.

Burlingame’s most tangible achievement occurred in the United States, where he helped forge one of the least-humiliating agreements of China’s unequal treaty era. The Burlingame-Seward Treaty of 1868 generally affirmed the privileges detailed in the 1844 and 1858 treaties between the Qing dynasty and the United States. In other ways, however, the treaty was equal and reciprocal in that it guaranteed citizens of each nation the rights to live, work, worship, and build schools in the other nation. The treaty allowed the Qing dynasty to dispatch consuls to U.S. ports—a sign of China’s gradual acceptance of Western diplomatic norms. The treaty also outlawed the “coolie trade” by which Chinese men were kidnapped to serve as laborers overseas. The treaty highlighted one of the most cherished ideals of the United States about its relationship with China, namely, that the United States rejected “intervention by one nation in the affairs or domestic administration of another.”

More controversially, the treaty welcomed Chinese immigrant labor to the United States (but did not contain provisions for emigrants from either nation to become citizens of the other). The U.S. domestic reaction to increased immigration, particularly in California, would result in the 1880 Angell Treaty, part of a series of increasingly stringent restrictions on Chinese labor culminating in the 1882 Exclusion Act. Far from improving relations, ultimately Burlingame’s treaty made the Chinese acutely aware of U.S. racism.

Anson Burlingame died while leading the Chinese delegation to Russia in February 1870. His sympathy for China’s plight was important in shaping the alleged special relationship of the United States with China. His career also illustrated Qing-era China’s tentative steps to engage in diplomacy on Western terms.

Butterfield and Swire Co, Ltd. was a British firm formed in 1866 to trade with China and Japan. Its business activities quickly expanded to include extensive shipping operations in China as well as manufacturing and services. The Swire Group, a contemporary multinational, remains an important investor in enterprises in China and Southeast Asia today.

Butterfield and Swire was a subsidiary of the British trading firm John Swire and Sons that was founded to expand the firm’s business to Japan and China. John Samuel Swire formed Butterfield and Swire by partnering with wool merchant Richard S. Butterfield in 1866 in order to sell British textiles in China and to buy silks and teas for export to England.

In 1867 Butterfield and Swire’s first office opened in Shanghai using the Chinese hong name (given to a commercial establishment or house of foreign trade in China) Taikoo 太古. The partnership between John S. Swire and Butterfield ended the next year, leaving Butterfield and Swire under the control of John Swire and Sons.

In addition to its trade activities, Butterfield and Swire was the agent for Alfred Holt’s Ocean Steamship Company (or Blue Funnel Line) in Japan and China. This association allowed Butterfield and Swire to expand its network of branch offices in China and provided the basis for its long involvement in shipping in Asia. Between 1870 and 1890 Butterfield and Swire added branches in Hong Kong, Tianjin, Hankou, Guangzhou (Canton), Fuzhou, Su’a, Jiujiang, Xiamen, and Qingdao as well as in Kobe and Yokohama. Responding to quickly changing economic conditions in China, within a few years of its founding the trading activities of Butterfield and Swire were subordinated to the management of new lines of business begun by the broader Swire organization. Most prominent of the new businesses was the China Navigation Company, a steamship company established in 1872 with capital from the Swire and Holt families. The China Navigation Company began on the Yangzi (Chang) River and later expanded its routes to the China coast, Japan, Australia, and Southeast Asia, often acting as a feeder service for the Ocean Steamship Company. China Navigation became one of the most prominent shipping companies in Chinese waters before World War II.

The Taikoo Sugar Refinery (established in 1881 in Hong Kong) was another Swire business; Butterfield and Swire managed its sugar shipments; China Navigation ships transported them. By the 1890s Butterfield and Swire had almost completely withdrawn from trade to concentrate on these associated businesses, which later included the Tianjin Lighter Company (1904), the Taikoo Dockyard and Engineering Company (1908), and the Orient Paint, Color, and Varnish Company (1934). Butterfield and Swire branches throughout China acquired agencies for other shipping companies, banks, insurance firms, and other businesses in addition to managing Swire affiliates.

World War II brought permanent change to Swire activities in China. After Japan attacked the U.S. naval fleet...
at Pearl Harbor, Hawaii, Japan seized most Swire properties, including China Navigation ships. After the war China’s government and shipping interests resisted the return of foreign ships to China’s coastal waters. Unable to continue its shipping business on the mainland, Swire shifted its base of operations to Hong Kong, completing the transition in 1953 when the firm transferred ownership of its remaining mainland properties to the government of the People's Republic of China. Today the Swire Group remains an important multinational firm, owning manufacturing, waste management, bottling, and real estate development interests in Hong Kong, Cathay Pacific Airways, and the China Navigation Company (now a Pacific Rim container line). Swire also has invested in businesses in the United States and Australia and in the 1980s began to reinvest in mainland China in a range of real estate, manufacturing, and aviation concerns.

Tales of the ill-fated “Butterfly Lovers,” Liang Shanbo and Zhu Yingtai, have roots in the Yuan dramatic corpus. Modern adaptations of this story in popular theatrical, musical, and cinematic venues often inject sociocultural themes ranging from advocacy for women’s education to cross-dressing and homoeroticism.

The earliest historical records of the tale of the lovers Liang Shanbo and Zhu Yingtai date back over a millennium. Zhu Yingtai, a young girl of a good family, cross-dresses to attend a school where she befriends a fellow student, Liang Shanbo. Without his ever becoming aware of her gender, they study together, and when he dies years later, she jumps into his tomb, an officially commemorated act of virtue on her part. In later vernacular versions Liang realizes during a reunion with Zhu at her home that she is a woman; he falls in love with her, but she has already been betrothed to a rich landowner. When Liang dies of lovesickness, Zhu passes Liang’s grave, the tomb miraculously opens, and Zhu jumps in to be united with Liang’s spirit. Two butterflies were said to dance upon the site, symbolizing the two lovers and their devotion to one another.

In the wake of the emergence of author-generated libretti in the Yuan dynasty (1279–1368), songwriter and dramatist Bai Pu treated the Zhu-Liang story in a now-lost Yuan zaju drama, Zhu Yingtai Marries Liang Shanbo in Death. Emotionally charged key scenes from other early dramatic forms—Yuan dynasty xiwen and Ming dynasty (1368–1644) chuanqi—depicting the imminent departure of Zhu and the reunion of the pair at her home survived in late Ming song miscellanies. The version contained in Feng Menglong’s (1578–1644) seminal collection of vernacular tales, Stories Old and New (1620), develops to the theme of deep and ultimately lethal passion in a manner not unlike the famous play Peony Pavilion (1598). During the Qing dynasty (1644–1912) numerous storytelling genres embraced the romantic tale, as did many regional operas. (Ironically, the role of the Liang Shanbo would have been played by a cross-dressing man in nineteenth-century Beijing Opera productions, which at that time were renowned for employing female impersonators.) Beijing, Guangzhou (Canton), Shaoxing, Huangmei, and Sichuan opera companies, among others, continue to feature it in their contemporary repertoires.

With the development of modern media, the story was newly rendered in films, animation, concertos, ballets, and spoken drama. Many of these adaptations have been wildly popular with audiences in China, Taiwan, and Hong Kong. Shao Zuiweng’s silent film The Heartrending Story of Liang and Zhu (Liang Zhu tengshi, 1926) starred actress Hu Die. Liang Zhu (1933) with Shaoxing opera star Yuan Xuefen was the first operatic film shot in color in the People’s Republic of China (PRC), contributing to the popularity of the story up to the Cultural Revolution (1966–1976), when the subject of personal love became anathema. Cast in the Huangmei opera style featuring female star Ling Bo, Hong Kong filmmaker Li Hanxiang’s Liang Shanbo and Zhu Yingtai (1963) also played to unprecedented sold-out crowds in Taipei, Taiwan.
Meanwhile “The Butterfly Lovers Violin Concerto” (composers: Chen Gang and He Zhanhao, 1958) synthesized Western instrumentation and Chinese tonalities in the tradition of pentatonic (consisting of five tones) romanticism. The piece premiered to great acclaim amid the social reforms of the early PRC period and served as the musical score for newer filmic and animated adaptations of the Liang-Zhu story in the 1990s and 2000s. These and other renditions vary in thematic emphasis, ranging from unrequited love and monogamous marriage to advocacy for women’s education, cross-dressing, and homoeroticism.

Cadre System

Gàn'bù zhìdù 干部制度

Similar to the system of China’s traditional civil service hierarchy, the cadre system refers to the fifteen ranks (previously twenty-five) by which Communist Party functionaries and other civil servants are categorized. Higher ranks have better salaries, medical treatment, and pensions, as well as access to more desirable living quarters.

In China the term cadre refers both to all Communist Party functionaries and civil servants in administrative institutions, public organizations, and armed forces and to persons in leading positions. It is important to differentiate between party, administrative, and military cadres. Because the term covers party and state leaders as well as village officials and police officers, it does not refer to a homogeneous group.

Beginning in 1956 cadres were classified according to twenty-five ranks (ji). Grade twenty-five was the lowest grade. The original classification was dependent on how long a person had attended the revolutionary movement or when a person was admitted into the Communist Party, as well as on one’s contributions to the revolution or “liberation.” The early classification was influenced by the Soviet cadre system but also by traditional ranking patterns of the civil service in imperial times.

The cadre system was remodeled in 1993 by the Provis-ional Regulations for Public Service into fifteen grades, starting with the prime minister at grade one and running down to ordinary officials at grades ten through fifteen. The grading is the same in each level of the party, in the People’s Congresses (parliaments), and in the Political Consultative Conferences. This same grading also regulates salaries and privileges. State cadres, that is, civil servants paid by the state, are put on the official schedule by the responsible personnel offices. Organization departments are responsible for party cadres. State cadres are paid out of the official budgets, whereas the other rural cadres have to be paid by extrabudgetary means. Each cadre grade is treated differently, with privileges increasing as grade level rises. “High cadres” (grade five and up) enjoy the greatest privileges as far as salaries, labor conditions, size, and standard of accommodation, medical treatment, and pensions are concerned. They also receive more servants paid by the state, a better official car with driver, the right to travel first class in trains and planes on official trips, and, last but not least, access to detailed information on China and foreign countries.

This hierarchical system is similar to China’s traditional civil service hierarchy, which was also divided into grades in what was known as the “ji hierarchy.” There were two main categories: civil and military service. From the Tang dynasty (618–907 CE) onward each category was divided into nine grades, each grade being divided into two classes, upper (shang) and lower (xia), for a total of eighteen ranks. Each grade was characterized by special insignias and salaries. The higher the rank, the greater the attendant privileges and nonmaterial advantages.

Today, as in the past, losing an official position or being excluded from the hierarchy means the loss of all kinds of privileges as well as a significant decrease in standard of living. Success in such a system and the social
security it offers make it attractive to become a member of the party and to join some kind of network that will guarantee advancement in the hierarchy.

CAI Yuanpei

1868–1940 Educator and Leader of the New Culture Movement

Cai Yuanpei, an accomplished student in the Confucian tradition, became part of China’s cultural and political elite at Beijing’s Imperial Hanlin Academy, where he was exposed to translated works from the West. As chancellor until 1926 of Beijing University, he was renowned for his commitment to intellectually diversity, center of the New Culture Movement.

Born in Shaoxing District, Zhejiang Province, to a family of bankers, Cai Yuanpei lost his father when he was only eleven years old. Despite declining fortunes, his family was able to support his education in Confucian traditions at several private schools. In 1892 Cai passed the highest level of the civil service examinations and earned the Jinshi degree at age twenty-four. In 1894 Cai was appointed as a compiler at Beijing’s Imperial Hanlin Academy, which brought him to the circle of national cultural and political elites. Also in Beijing he gained easy access to translated works from the West, including Yan Fu’s translation of Thomas Huxley’s Evolution and Ethics, which Cai read more than once.

Cai’s most significant impact on modern Chinese history was his tenure as chancellor of Beijing University between 1917 and 1926. He adopted an inclusive policy of staffing the faculty with people of widely diverse intellectual orientations, hence creating a vibrant cultural environment that made Beijing University the powerhouse of the New Culture Movement. In hopes of training a new generation of well-rounded intellectuals, he especially encouraged physical and aesthetic education in addition to science and technology in hopes of training a new generation of well-rounded intellectuals.
science and technology. He was a vocal advocate of the vernacular and argued for the independence of education from political intervention.

During the reorganization of the Guomindang (Chinese Nationalist Party) in the early 1920s, Cai was in Europe but was elected in absentia to the Central Supervisory Committee. Although in 1927 he supported the Guomindang’s suppression of the Communists, he later regretted the brutal killing of the radicals. He was appointed president of the National Academia Sinica in 1928 when it was founded by the national government. In 1932 Cai joined with other liberals to organize the China Civil Rights Protection Alliance in protest of the national government’s repression of dissidents. Cai’s health began to decline in the mid-1930s, and he went to Hong Kong after the War of Resistance against Japan broke out in 1937. He died from a stomach tumor in 1940.

Calendar

Yínlì 阴历

The ancient Chinese calendar is still used to mark religious and traditional holidays and festivals. Its form is derived from astronomical observations of the longitude of the sun and the phases of the moon. Unlike other calendars, it does not count years in an infinite sequence.

China has a long tradition of astronomical observation. The main calendars used in the Far East were Chinese in origin until the nineteenth century; today such long-established calendars still are used to mark religious and traditional holidays and festivals; the Gregorian calendar regulates only civic affairs.

The origin of the Chinese calendar is steeped in myth; the legendary Emperor Huangdi supposedly created the calendar in 2637 BCE. But historical evidence dates the invention of the calendar well into the fourteenth century BCE. Its form is lunisolar (derived from astronomical observations of the longitude of the sun and the phases of the moon), therefore its year matches the tropical year (the period between two successive times when the sun reaches its most northerly point in the sky), and its months coincide with the synodic months (the period between two successive full moons or two conjunctions of the sun and moon).

An ordinary year in the Chinese calendar, as in the Jewish, has twelve months, whereas a leap year has thirteen months. As a result, an ordinary year has 353, 354, or 355 days, and a leap year has 383, 384, or 385 days.

This Qing dynasty illustration shows yet another version of the calendar-creation legend. In this legend the Xi and He brothers receive a government commission from emperor Yao to organize the calendar with respect to the celestial bodies.
To determine the Chinese year, first the dates of the new moons are established. A new moon is interpreted as a completely “black” moon (when the moon is in conjunction with the sun), not the first visible crescent, as stipulated in Islamic and Jewish calendars. The date of a new moon is the first day of a new month. Calculated next are the dates when the sun’s longitude is a multiple of 30 degrees. These dates, called the “principal terms,” are used to calculate the number of each month. Therefore, each month carries the number of the principal term that occurs in that month.

All astronomical observations are made for the meridian 120 degrees east of Greenwich, England, which approximately aligns with the east coast of China. The Chinese calendar, unlike other calendars, does not count years in an infinite sequence. Instead, years have names that are repeated every sixty years. Within a sixty-year cycle each year is assigned a name composed of two parts: the celestial stem, the terms of which cannot be translated into English, and the terrestrial branch, the terms of which correspond to animals of the Chinese zodiac. This method of using a sixty-year cycle is ancient: The cycles are numbered from 2637 BCE, when the Chinese calendar supposedly was established.

Chinese calligraphy (from the Greek kalligraphia, “beautiful writing”) is the art of writing that educated Chinese have practiced for millennia. All students of written Chinese practice calligraphy, but becoming a good calligrapher requires practice, self-discipline, and an artistic sense. Chinese calligraphy, therefore, is more than just the mere art of penmanship.

The Chinese Character

Written Chinese is ideographic and in some cases pictographic. Thus each Chinese character is a monosyllabic word that conveys an idea. Characters, insofar as they are sometimes pictographic, also provide a visual expression of the ideas that they represent in a way that purely phonetic scripts do not. Characters, each composed of a series of strokes, make up words when written in a particular order. No matter how many strokes a character may be composed of, it must fit perfectly inside an imaginary box that is the same size as those of the characters preceding and following it. A character usually has two components:

Calligraphy painting by C. C. Wang. Calligraphy is one of China’s earliest and most revered art forms, a symbol of culture, education, self-discipline, and erudition. The quality of one’s calligraphy was thought to provide insight into one’s moral character. Calligraphic writing on paintings, a means for imparting wisdom or advice, was often integral to the composition of the images. Photo by Joan Lebold Cohen.
a radical that indicates meaning in a very broad sense, and a phonetic component that indicates sound, also in a broad sense. These components may be side by side or one on top of the other, inside the imaginary box within which each character is composed. Calligraphy is the art of writing these characters.

**History of Writing and Calligraphy**

Historically, writing and power have been intimately related in China, and calligraphy has been of much greater importance there than penmanship has been in Western societies. The earliest examples of writing in China appear on oracle bones from the Shang dynasty (1766–1045 BCE). These oracle bones were tortoise shells and scapula of mammals, etched with questions for the gods and then held over heat until they cracked. Shamans (magicians), who had written the inscriptions in the first place, interpreted the cracks as divine answers to the questions. People with the ability to write in ancient China, therefore, had the power to communicate with Heaven and to interpret Heaven’s will. Early Chinese rulers, eager to empower themselves in every possible way, surrounded themselves by those who could write and help them communicate with Heaven.

Although, as the oracle bones show us, writing existed in China at least three thousand years ago, there was not a unified written language in China until the third century BCE. At that time, Shi Huangdi (c. 259–210 BCE), the first emperor of the Qin dynasty (221–206 BCE), who was trying to reshape the numerous kingdoms of the Chinese landmass into a unified empire, standardized writing. The creation of a single, unified written language in a nation full of spoken dialects, where there was no universally comprehensible spoken language, made the written language that much more important.

Over time education in China’s written language became essential to participation in government, and an imperial examination system evolved to test candidates’ skill in written expression. From the Tang (618–907) to the Qing dynasty (1644–1912), calligraphy was considered an important criterion for passing all three levels of these civil service examinations. The quality of one’s calligraphy was thought to provide insight into one’s moral character. Beautiful calligraphy became a symbol of culture, education, self-discipline, and erudition.

Certain people became known for their calligraphy, and the calligraphy of other people became known because the calligraphers themselves were famous or powerful. Writing on paintings, memorials, and other materials became a way for superiors to impart wisdom, advice, and injunctions to their inferiors. Virtually any literate person recognized the calligraphy of the emperor and the most important government figures of the time.

**Calligraphic Styles**

A variety of styles of calligraphy, or scripts, evolved over time, each coming to be identified with particular types or styles of writing. The script that became standard during the reign of Shi Huangdi is known as small seal (xi-aozhuan) script. This script is difficult for people to read
Calligraphy today and is generally used only in works of art. Among other scripts that have evolved, the most common is regular (kaishu) script, in which each stroke of a character is clearly written. Because of its clarity, regular script is generally used for printing. The clerical (lishu) style was developed during the Han dynasty (206 BCE–220 CE). It is most commonly used today in inscriptions on monuments and public buildings. Writers of informal notes or letters probably use the running (xingshu) style of script, in which the separate strokes of a given character are often run together. A variation on the running style is the grass (caoshu) style, which actually omits strokes and joins separate characters together. The grass style was particularly popular among literati in the late imperial era.

Calligraphy as Art

Chinese calligraphy is ornamental. Its beauty lies in both the concepts expressed and the form of expression. Throughout the Chinese world, people display decorative calligraphy in homes and businesses. Couplets, often written on strips of red paper, hang at the entrances of homes; lucky characters are pasted on the walls and windows of shops, restaurants, and homes at the Chinese New Year; and scrolls of calligraphy hang in living rooms.

Perhaps because calligraphy is an art form and a means of self-expression rather than simply a vehicle for conveying meaning, works of art—such as paintings, sculptures, and buildings—are themselves often adorned with calligraphy. In many cases the inscriptions on paintings, and the etchings on buildings, monuments, and places of natural beauty are expressions of appreciation, commentaries, or labels appended by later owners or observers (often the emperor). These calligraphic additions are not generally seen as detracting from the original piece, but as adding something to it.

Contemporary Calligraphy

During the twentieth century, China underwent several attempts to simplify the written language. Language reformers, hoping to increase literacy, introduced both phonetic scripts using roman letters and simplified characters, the forms of which, interestingly, are derived in...
many instances from *caoshu*, or the grass style of calligraphy. Although the phonetic systems have not become especially popular, more than two thousand simplified versions of commonly used characters were introduced by the People’s Republic of China (PRC) as the official written form between 1956 and 1964. Their use in the PRC has relegated to the past the more complex forms of characters and the art of writing them for most Chinese.

Nonetheless, calligraphy has remained important in post-1949 China, and the calligraphy of famous Communist Party members can be seen on various signs throughout China. The characters for the name of the newspaper called the *People’s Daily* (*renmin ribao*), for instance, are printed in the calligraphy of Mao Zedong (1893–1976). The presence of Mao’s calligraphy on the front page of every edition of the *People’s Daily* shows the world that the paper benefited from his patronage.

While the forms of characters may have changed during the twentieth century, the functions of calligraphy have remained essentially the same. Calligraphy is the artistic expression of the power of language by the individual. Both the form and content of calligraphy inform the reader or viewer about the morality, education, and dedication of the calligrapher.

The Canada China Business Council promotes trade and investment between the two nations through programs and events that disseminate market insight and information.

A private, nonprofit, membership-based organization, the Canada China Business Council (CCBC) was incorporated in 1978 to promote and assist in trade and investment between Canada and China. It has become a preeminent authority on China-Canadian trade.

CCBC has approximately three hundred members that include large Canadian and Chinese firms in addition to small and midsized entrepreneurs from both countries. Membership is about equally divided between companies and individual members that represent a variety of sectors, including financial services, legal services, information and communications technology, education, manufacturing, construction, transportation, mining, and energy.

The council acts as a Canadian chamber of commerce in China, providing business networking opportunities and advocating on behalf of the business community. Headquartered in Toronto, it also has offices in Vancouver, Beijing, Shanghai, Nanjing, Shenyang, Chengdu, and Shenzhen. Through this network, the CCBC gathers market information and connects its members to opportunities in many of China’s emerging regions. In addition, the CCBC also operates chapters in Beijing and Shanghai. Established in the 1990s, these chapters sponsor events such as networking functions, seminars, and roundtable discussions for Chinese and Canadian business people, allowing for the establishment of a broad communication forum within China and Canada.

To facilitate trade and investment between the two nations, the council institutes programs and events that disseminate market insight and information, support business and logistics services, and uncover leads for business opportunities in Canada and China. Along with the CCBC’s annual general meeting, these functions are forums for bilateral interchange and are attended by both Canadian and Chinese business and government leaders.

The council is the largest Sino-Canadian business association, with a board of directors that includes former Canadian ambassador to China Howard Balloch and three top officials of Power Corporation of Canada, including the presidents and CEOs of its financial services division and technology investment divisions. The council has thirty directors.

For much of the twentieth century, the Chinese were the largest visible minority in Canada, and this has remained true in the first decade of the twenty-first century. According to Statistics Canada, a department of the Canadian government, 16 percent of all immigrants to Canada came from China from 2002 to 2004. Currently there are approximately 1 million Chinese immigrants in Canada, and the majority reside in Ontario and British Columbia—the home provinces of Toronto and Vancouver, respectively, and locations of CCBC’s two Canadian offices.

Chinese Immigration to Canada

In the early twentieth century, Canada passed numerous laws restricting and even preventing Chinese immigration. Some of the laws, like the one below, explain the Head Tax placed on Chinese immigrants to Canada.

TAX AND EXEMPTIONS

7. Every person of Chinese origin, irrespective of allegiance, shall pay into the Consolidated Revenue Fund of Canada, on entering Canada, at the port or place of entry, a tax of five hundred dollars, except the following persons who shall be exempt from such payment, that is to say: —

(a) The members of the diplomatic corps, or other government representatives, their suites and their servants, and consuls and consular agents;

(b) The children born in Canada of parents of Chinese origin and who have left Canada for educational or other purposes, on substantiating their identity to the satisfaction of the controller at the port or place where they seek to enter on their return;

(c) Merchants, their wives and children, the wives and children of clergymen, tourists, men of science and students, who shall substantiate their statues to the satisfaction of the controller, subject to the approval of the Minister, or who are bearers of certificates of identity, or other similar documents issued by the government or by a recognized official or representative of the government who subject they are, specifying their occupation and their object in coming into Canada.

Further Reading

The Canton Fair, officially known (until 2007) as the China Export Commodities Fair and afterwards as the China Import and Export Fair, is China’s No. 1 fair. It has the longest history, largest scale and variety of products, largest attendance, and greatest business representation of any such fair in China. It has promoted economic and trade cooperation and technology exchange between China and the world.

To develop China’s exports to capitalist countries, the Chinese government held three export exhibitions in Guangzhou (Canton) from 1954 to 1956. Building on these exhibitions, the first session of the Canton Fair was held in Guangzhou in 1957. Since then two sessions of the fair have been held every year in Guangzhou. One session starts on 15 April, and the other starts on 15 October. From 1957 to 1981 every session lasted a month. From 1982 to 1988 the sessions were shortened to twenty days; and beginning in 1989 they were shortened to fifteen days. Every session was then divided into two phases with a four-day break between 21–24 April and 21–24 October. The Canton Fair’s 104th session, held in October 2008, was arranged in three theme-based phases, allowing for more business participation; the first phase was held from 15–19 October, the second from 24–28 October, and the third from 2–6 November.

In addition to the traditional method of bringing sample products to the fair, the fair now has an online component. Its website, in operation since 1999, has become a platform for international business communication in what can now be called the “Never Ending Canton Fair.”

Since the first session in 1957 China has experienced natural and political disasters, such as the Great Chinese Famine from 1960 to 1962, the Cultural Revolution (1966–1976), the SARS (severe acute respiratory syndrome) epidemic in 2003, and the Sichuan Province earthquake of May 2008, but the Canton Fair has never been canceled. This is highly unusual in the history of international exhibitions.

The China Export Commodities Fair was renamed the “China Import and Export Fair” (CIEF) at its 101st session on 15 April 2007. The change was part of China’s efforts to improve its imports from trading partners and narrow the trade gap.

**Organization**

The China Foreign Trade Center (CFTC) is in charge of the organization, management, and operation of the Canton Fair. Its predecessor, the Chinese Export Commodities Exhibition Hall, was founded in 1957. It was renamed the “Guangzhou Foreign Trade Center” in 1979, the “China Foreign Trade Center (Guangzhou)” in 1986, the “China Foreign Trade Center (Group)” in 1988, and finally the “China Foreign Trade Center” in 2001. The name changes reflect its institutional reform from a state-owned
enterprise under the direct control of the Ministry of Foreign Trade and Economic Cooperation to a government-sponsored institution that operates independently and has the full responsibility for its profit and loss.

Exhibition Halls

The Liuhua Complex, an exhibition hall established in 1974, hosted each of the Canton Fair sessions until April 2004. Because of the increasing size of the fair, construction began on a new exhibition hall, the Pazhou Complex, which was partly finished and used for the ninety-fifth Canton Fair in April 2004. Since then all of the fairs (including the ninety-sixth Canton Fair in October 2004) have been held simultaneously in the Pazhou Complex and the Liuhua Complex. The Parzhou Complex, completed at the end of 2008, covers an area of 810,000 square meters with a structural area of 1.1 million square meters; it has an indoor exhibition area of 350,000 square meters—enough space for 17,500 exhibition booths—making it the third-largest exhibition hall in the world.

Importance to China’s Economy

The Canton Fair has been the most important channel for Chinese enterprises to enter the international market. In the 1960s and 1970s the proportion of trade done at the Canton

Sculptures of Buddha and Bodhisattva (Guanyin) for export at Canton Trade Fair, Guangzhou, China, 1979. In the last three decades the international fair has expanded its physical quarters with brand new exhibitions halls, its reach with an online component, and its offerings, with an increasing variety and number of Chinese brand name.

PHOTO BY JOAN LEBOLD COHEN.
Fair, relative to China’s total exports, increased steadily. From 1965 to 1979 the proportion averaged 34 percent, and in 1972 it hit a high of 54 percent. Since China’s opening to the world in 1979 Chinese enterprises have had many more opportunities to enter the international market. The Canton Fair’s relative importance to China’s exports has therefore been decreasing steadily. Since 2003 less than 10 percent of China’s annual exports come from the Canton Fair. But the number of visitors and the business turnover of each session of the fair continued to increase steadily until the 101st session in April 2007, and despite some gradual declines in the following two sessions, statistics for the 104th session in October–November 2008 were better than predicted, especially given the global financial crisis. With the rapid increase in the volume of China’s international trade the Canton Fair, therefore, remains China’s No. 1 fair.

102nd Canton Fair, 2007

The 102nd Canton Fair, which was held 15–30 October 2007, had 189,500 visitors from 213 trading countries and regions, and the total export turnover of that session reached $37.45 billion. The number of visitors decreased by 8.3 percent from the highest level, achieved at the 101st session, but the export figure hit a high with an increase of 2.9 percent over the 101st session in April 2007 and a 10 percent increase over the 100th session a year earlier. Mechanical and electrical products occupied the lion’s share of the deals, and light industrial products occupied second place. Several commodity categories that are undergoing tariff rebate policy adjustments suffered a dip in their transactions. Categories included garments (decreased by 8.8 percent), footwear (decreased by 9.2 percent), toys...
(decreased by 10.7 percent), and motorcycles (decreased by 30.7 percent).

104th Canton Fair, 2008

The 104th Canton Fair, which was held from 15 October to 6 November, 2008, had 174,562 visitors from several hundred trading countries and regions, and the total export turnover of that session reached $31.55 billion. Although this was a decrease in the number from the previous year, given the downturn presented by the global financial crisis, the result was better than expected. Moreover, at this fair there was an increase in Chinese brands on display, as well as an emphasis on higher technology products. It is clear that China is attempting to move up the technological ladder.

Outlook in the Twenty-First Century

The Canton Fair is a long-standing showcase for products made in China and, increasingly, for foreigners seeking to sell their products in the Chinese market. Its fame comes partly from its long history and partly from China’s increasing importance in world trade. While the fair is a somewhat outdated phenomenon in an age of e-commerce, and there are many other ways now for producers to sell their products, the Canton Fair will continue to be an important forum for international trade in the twenty-first century.

Canton System

The Canton System refers to the Qing dynasty’s practice of confining Westerners who wanted to trade with “The Middle Kingdom” to the confines of the city of Canton (now known as Guangzhou), believing they would be easier to control if confined to one area. The Chinese mandarinate kept extremely tight control of foreign trade, keeping a careful eye on foreigners once they set foot on Chinese soil.

The city of Guangzhou (Canton) is located at the mouth of the Canton River just before the river flows into the Boca Tigris estuary, the large waterway that separates Macao and Hong Kong. The geostrategic site of the city gives it a great military and commercial importance beyond its privileged position as the capital of Guangdong Province and the seat of the governor of the province.

Eighty-five years prior to the opening of China in 1842, the Chinese empire had determined to limit the foreign trade of the country to Guangzhou because the city constituted an easy access to the foreign traders (“barbarians of the Western Seas”) and especially because the traders were easier to control if they were in one location rather than roaming the entire Middle Kingdom unhindered.

That was the foundation of the Canton System, which coerced Western nations who wished to trade with China to confine themselves to Guangzhou and its regulations under the stultifying close supervision of the Chinese mandarinate (the office of a public official). The tight control of foreign trade was not only a technical issue of watching the steps of the foreigners after they set foot in Chinese territory, but also a cultural issue derived from Chinese worldview. China never gave high precedence to international trade, preferred its economic autarky (self-sufficiency) over dependence on others, and acted under the conviction that since it was the center of the universe (Zhong guo, literally “Middle Kingdom”) and their emperor had universal kingship, any foreign barbarian who came to China had to come in submission, provide his goods as if they were part of the tribute that he owed to the Ruler of the Celestial Empire, and take back with him the “presents” that the emperor bestowed on him.

British Domination

Although a Chinese official (hoppo) controlled that trade and levied hefty taxes on it, it was in practice conducted by a monopoly of Chinese private companies. These companies—restricted to about twelve in number and known as hong merchants—paid the authorities well for their lucrative permits to trade with their private foreign counterparts, who established parallel “factories” that represented major Western trading companies.

The British, who dominated that trade, were represented by the East India Company, whose monopoly was to be abrogated on the eve of the Opium War in later years. British domination of that trade was derived from the proximity to the China coast of the major Indian ports that were under British dominion. Instrumental in
facilitating that trade were Chinese compradors (buyers), who were accompanied by a crowd of translators, money changers, and clerks. These trade intermediaries between China and the West were to emerge as a powerful mediating class that took the lead in the pioneering modernization of the country.

The hong were organized into a guild (co-hong), which not only paid heavily for its monopoly on trade but also was held responsible to authorities for the conduct of foreigners while they were in Chinese territory during the trading season (October to January), which avoided the seasonal hurricanes (typhoons). All contracts were signed one year earlier and carried out during the trading period when the foreigners arrived in Cantonese waters, loaded the Chinese goods, mainly tea, silk, pottery, lacquer, and rhubarb, and left behind a trickle of British goods (furs, metals, wool) and shiploads of silver currency. When in the early nineteenth century the British began substituting the cheap opium that they grew in nearby Bengal, India, for the silver that had depleted their treasuries since tea had become their national beverage a century earlier, they created massive opium addiction in China, which escalated into the First Opium War (1839–1842).

After the goods were exchanged and paid for, the foreign ships sailed to Macao at the mouth of the Boca Tigris, were provided with food and water, and, after registering their orders for the year after, set sail for their European or U.S. destinations. Western powers, far from adapting to Chinese ways, sought to break the confinement of the Canton System so as not only to spread trade all over the long Chinese coast but also to sail inland along the Yangzi and the Canton rivers and so widen their markets with the help of the compradors whom they were to cultivate in the major ports. But not until the First Opium War broke out in 1839 against the background of the British attempting to turn the devastating opium trade into a legal and unlimited one, were five more ports opened under the Nanking Treaty, which put an end to the three-year war.

Aftermath

The opening of new ports, which forced China into the international trade system and gave a permanent base in Hong Kong to the British, brought an end to the Canton System after this major port became only one of the five open trading centers. Moreover, the open ports grew into foci of interaction between Chinese and Westerners since the latter obtained concessions that gave them virtual extraterritorial rights and an incentive to widen their rule on Chinese soil. The culture of treaty ports was born and a decade later brought about the opening of yet more ports in the hinterland and the almost complete subjugation of China to foreigners for the century to come.

Fifty-five million Chinese speak Cantonese (Yue), which makes Cantonese the second-most-spoken language in China after Mandarin. But is Cantonese—and Mandarin for that matter—a language or a dialect of a larger Chinese language? Linguists have long debated the point.

Many people think of Mandarin (putonghua, literally “commoner’s language”) as the modern standard Chinese language. Chinese, in fact, is a group of many languages and dialects, including Cantonese, or Yue. Cantonese is the tongue of some 55 million speakers in China and about 20 million speakers around the world. Cantonese is usually considered the language of southern China; Mandarin, the language of the north. Cantonese is spoken extensively in Guangdong Province, Guangxi Zhuang Autonomous Region, Macao, and Hong Kong. Cantonese is also the most common form of Chinese heard in Chinatowns around the world.

Language or Dialect?

Cantonese belongs to the Sinitic branch of the Sino-Tibetan family of languages. This language family contains some 250 languages spoken in East Asia. The Sinitic group comprises the seven recognized major language groups and numerous dialects of China. Most of these languages are not mutually intelligible; that is, speakers of Cantonese and Mandarin cannot understand each other. Whether Cantonese is a true language or a dialect is an ongoing debate among linguists. (For convenience, language will be used here).

Yuehua (Yue speech) is the formal name given by linguists to the Cantonese language, particularly when referring to the many dialects, not just to the standard Cantonese that is the everyday speech of the cities of Guangzhou (Canton) and Hong Kong. Guangdong and Guangxi (a province before it became Guangxi Zhuang Autonomous Region) are often referred to as the liang guang (two Guangs), liang yue (two yues), or Lingnan (south of the mountain range). The forms of Cantonese are quite diverse. Even in Guangzhou and the surrounding area, there are sharp dialectical differences. Linguists have identified seven dialect areas in Guangdong, most of them in the Zhu (Pearl) River delta and western Guangdong: Guangfu (the speech of Guangzhou), Yongxun, Gaoyang, Siyä (four districts), Goulou, Wuhua, and Qinlan. These are spoken around specific geographical areas.

Origins of Cantonese

At an unknown time, a group of Sinitic people moved across the Nan Ling Mountains in southern China into the Lingnan, or what became the provinces of Guangdong and Guangxi. The indigenous peoples of the Lingnan were eventually assimilated into new Sinicized cultural and language groups. The various Yue-speaking people originated in this way. The basic ideograph yue means...
“to exceed, to go beyond.” It has been extended to mean “frontier,” or “beyond the borderland.”

Separated from the rest of China by the high Nan Ling range, which runs east to west, the people of Guangdong and Guangxi have considered themselves different from other Sinitic peoples. Cantonese speakers are more likely to identify themselves as Tongyen (Yue) or Tangren (Mandarin), that is, “Tang persons,” rather than Hanren, or “Han persons,” which is how most Chinese identify themselves. This is mainly because it was during the Tang period (618–907 CE) that the homeland of the Yue people became part of the Chinese cultural realm. The Cantonese traditionally speak of classical written Chinese as Tong man or Tang wen (Tang language). Cantonese is closer to ancient Chinese than Mandarin is.

**Characteristics of Cantonese**

Standard Cantonese, the dialect spoken in Guangzhou and Hong Kong, demonstrates a number of phonetic (speech sounds) and grammatical features that set it apart from other Sinitic languages.

Cantonese retains the ancient final consonants that have been lost in the north. These include \(-m\), \(-p\), \(-t\), and \(-k\). The retroflex consonants that characterize Northern Mandarin are absent. (Retroflex sounds are produced with the tongue curled up and back until it touches the hard palate. English has no retroflex consonant sounds). Cantonese has syllables that begin in \(ng\). Cantonese lacks any phonetic distinction between the sounds \(s\) and \(sh\), \(ts\) and \(ch\), and \(ts'\) and \(ch'\) (these last two are not heard in English.) In Cantonese there is a separate series of long and short vowels. Additional vowel sounds and the final consonants in standard Cantonese mean that Cantonese has almost twice the number of syllables that Mandarin has.

While standard Mandarin has four tones, the number of tones in Cantonese varies according to the dialect. Standard Cantonese has nine tones. Speakers in Zhongshan County, located between Guangzhou and Sze-yap, use only six tones. In other counties there are ten or even more tones. Cantonese, unlike many of the other southern languages, has little tone sandhi (changes in tone when tones run together in speech flow). It has none of the unaccented toneless neutral syllables that form parts of compounds and other connected utterances in standard Mandarin. There is a pattern in Cantonese, however, in which a change in a word’s tone can be used to modify it to mean a related term. One example is the word for tobacco, which is a tonal variant of the word for smoke.

Cantonese also differs from standard Chinese in grammar. One difference is the ordering of the indirect and direct object in a sentence. In Mandarin the ordering is similar to that in English. For example, the sentence “give me (indirect) something (direct)” would have the same sequencing in both Mandarin and English. For standard Cantonese, the ordering is more like “give something (direct) me (indirect).”
Linguists believe that the Cantonese spoken in southern China has been heavily influenced by the languages of the peoples who lived there before the coming of the Sinitic peoples. Linguists believe that these languages were related to the Tai branch of Sino-Tibetan. This influence is apparent in word order and grammar. In Tai-related languages, as in Cantonese, the adjective follows the noun. In Mandarin, as in English, the adjective precedes the noun. This is why many two-character terms in Cantonese appear to readers of Mandarin to have been put together in backward sequence. The pattern is especially evident in some dialects of Cantonese, particularly in southwest Guangzhou.

Because the language is so flexible, Cantonese has been able to absorb many foreign words, including words from English, such as *salad* (sah-lud), *bus* (baa-see), and *taxi* (dik-see). Oddly enough, however, Cantonese has not borrowed as much from northern Chinese as, for instance, the Wu or Min languages have.

Cantonese and Mandarin also differ in terms of written Chinese characters. This is in part because new characters have been added to stand for the words that are apparently exclusive to Cantonese. In some instances characters that are no longer in use in Mandarin have been used to transcribe words in Cantonese. This means that there can be written texts that are uniquely Cantonese that would be difficult for someone from northern China to read without a special study of Cantonese.

### Cantonese Speakers

The best known and most populous of the speakers of Cantonese are the people of Guangzhou and Hong Kong. The language form that these people speak is composed of many dialects, known to linguists as the Yuehai dialect of Yuehua. The most influential dialect is standard Cantonese. Linguistically, the Yuehai region is rather fragmented, but the core is the so-called Three Districts (Sam-yap in the vernacular) around Guangzhou. The districts are Namhoi, Punyu, and Shuntak.

Other well-known speakers of Yuehua are people of the Four Districts, or Sze-yap (Siyi in Mandarin). The Sze-yap dialect has many features that mark it from standard Cantonese so that speakers of the two would find it difficult to understand each other. Both the tonal pattern and vowels are different.

*Guinan* is the name usually given to the Cantonese dialects of the interior of Guangxi. Among the Guinan are dialects also, which can be called subdialects. They are known as Wuzhou, Guixian, Cangwu, Guiping, and Tengxian. Many of these Guinan subdialects have pronunciations of certain sounds that are unlike those of other Cantonese dialects. There are initial consonants, like *b* and *d*, that might not be found in standard Cantonese.

The general impression among the Chinese is that, with the exception of speakers of standard Cantonese, most Cantonese speakers have not played much of a role in the cultural development of China. Consequently, the Guangxi part of the Yue region has been treated more as a cultural backwater, even by other Cantonese speakers. Yet Cantonese speakers have contributed greatly to the large cultural mix known as China.

Cao Xueqin wrote The Story of the Stone, the novel that was the basis of The Dream of the Red Chamber, one of the most celebrated novels in the history of Chinese literature.

Cao Xueqin (Ts’ao Hsueh-ch’iin) was born in Nanjing into a powerful and wealthy family. Shortly after Cao’s birth, the family became involved in political intrigues, falling into disgrace and financial ruin. Beginning in 1742 Cao lived in poverty in the western suburbs of Beijing, making a little money selling his own paintings. It was there that he wrote Shitou ji (The Story of the Stone).

Although the manuscript was left unfinished when he died, handwritten copies with eighty chapters began to appear before long. In 1792 the novel was printed with an additional forty chapters, usually attributed to Gao E, under the title Honglou meng (The Dream of the Red Chamber). It is one of the most celebrated novels in the history of Chinese literature. The novel, which has some strong autobiographical elements, focuses on the downfall of the Jia family. The principal characters are Baoyu, who is born from a stone into the Jia family, and Daiyu, who is deeply but unhappily in love with Baoyu. The decline of the Jia family follows the death of one of the daughters who was an imperial consort, but in the end the imperial favors are restored, and Baoyu passes the imperial examinations. The novel has been translated into English several times.

CAO Yu
Cáo Yú 曹禺
1910–1996  Playwright

Author of the classic Chinese play Leiyu (Thunderstorm), Cao Yu is considered one of the most important playwrights of twentieth-century China. He was instrumental in the acceptance of the Western style play into the Chinese theater tradition, and his plays are still popular in China today.

Cao Yu was China’s most accomplished playwright of the twentieth century. Born as Wan Jiabao in Qianjiang County of Hubei Province, Cao Yu relocated to Tianjin with his parents when he was young. In 1922 he went to Nankai Middle School, where three years later he joined its Xinjushe (Society of New Theatric Arts) and played a key role in it. A lover of literature, he read a great deal of Chinese and Western classics. In 1928 he enrolled in the Department of Political Science at Nankai University, Tianjin, and transferred to the Department of Foreign Languages at Tsinghua University in Beijing the next year. There his interest in Western theatrical arts and traditional Chinese operas intensified. He was particularly drawn to Shakespeare and classical Greek and Roman tragedians.

In the year of his graduation in 1933, he finished his debut work, Leiyu (Thunderstorm), which became a classic. He used his pen name Cao Yu instead of his real name;
Cao yu are the two parts that form the traditional character wan, his last name. In the same year Cao Yu enrolled in the Graduate College of Tsinghua University to study theater. The next year he became a teacher at Tianjin’s Hebei Normal School for Women, where he completed his second script, entitled Richu (Sunrise), which turned out to be another classic. In 1936 Cao Yu was hired by the National Institute of Dramatic Art in Nanjing to teach playwriting and Western drama. That year he wrote Yuanye (The Wilderness). When the War of Resistance against Japan (1937–1945, known outside China as the Second Sino-Japanese War) broke out Cao Yu took refuge with his school in Chongqing, a city in Sichuan Province behind the frontline. He served as a member of the Council of National Anti-Japanese Association of the Literary Circles and worked as a playwright for a movie studio. His works of the time included Tuibian (Metamorphosis), Dujin (Gild), and Beijingren (Beijing Man). In 1946 he was invited by the State Department of the United States to teach as a visiting scholar. A year later he returned to China and was hired by the Shanghai Experimental Drama School. He published his play Qiao (Bridge) and wrote and directed the movie Yanyang tian (Sunny Skies) produced by the Shanghai Wenhua Film Company.

After the founding of the People’s Republic of China in 1949, Cao Yu came to Beijing from Shanghai
via Hong Kong. He served successively as the associate dean of the Central Academy of Drama (1950), director of the Beijing People’s Art Theater (1952), and secretary of the Secretariat of Chinese Authors Association (1956). In 1956 he finished his play Minglang de tian (Bright Skies) and co-authored Dan jian pian (Courage and Swords) in 1960. Two years later he planned to write a play entitled Wang Zhaojun but was interrupted by the Cultural Revolution (1966–1976), during which he was forced to work as a gatekeeper and often publicly humiliated. Not until 1978 was he able to complete the play.

Cao Yu was pivotal to giving a foothold to the Western-style play after its introduction to China, where it is known as huanju (verbal drama) as opposed to the traditional Chinese operas that require singing. His plays still hold the limelight on the Chinese stage. Another contribution of Cao Yu was his masterful integration of Western and Chinese theatrical arts.

取长补短
Qǔ cháng bǔ duǎn
For more than two thousand years caoyun was the centralized transportation system used by central governments of imperial China to collect grain—an important form of tax levied on agricultural land—and transport it to locations such as capitals, the metropolitan garrison, the court, and the metropolitan bureaucracy. The caoyun system consisted of water transportation and land transportation.

The centralized caoyun system of water and land transportation was established during the Qin dynasty (221–206 BCE) to meet the consumption needs of the government and military and to distribute grain as welfare to people who needed it. During a warring period with a neighboring tribe to the north, Qin Shi Huang—who was the first emperor of the Qin dynasty and unified China—ordered the Linqu Canal to be built. This canal connected the Li Jiang River in Guangxi and the Xiang Jiang River in Hunan, enabling faster supplying of troops.

By the late Qing dynasty (1644–1912), the caoyun system was out of use. One of the obvious reasons for its demise was the destruction of the Grand Canal during the lengthy civil war between Hong Xiuquan’s Taiping Heavenly Kingdom (1851–1864) and the Qing government. In fact, in the late nineteenth century China’s modernization and the increasing use of steamships and railways made the caoyun system obsolete.

From the Qin dynasty to the Qing dynasty, a period of about two thousand years, the caoyun system played an important role both politically and economically. The caoyun system was developed and improved throughout the major dynasties in between—the Han (206 BCE–220 CE), Sui (581–618 CE), Tang (618–907 CE), Song (960–1279), Yuan (1279–1368), and Ming (1368–1644).

For instance, during the Han dynasty the Cao Qu Channel was built, running parallel to the Wei River. Hence, the distance of water transportation between the grain-producing areas and the capital city Chang An (Xi’an) was significantly shortened. The amount of grain tribute able to be shipped to the capital had once reached 6 million shi (1 shi is about 62.5 kilograms) a year. The average yearly amount was about 4 million shi, according to historian Sima Qian’s Records of the Grand Historian.

Although the Sui dynasty spanned a relatively short period, its contribution to the caoyun system was significant. The newly dug canals of Guang Tong, Tong Ji, Shan Yang, and Yong Ji had connected five large rivers: Hai, Huang (Yellow), Huai, Yangzi (Chang), and Qiantang. As a result, a great water network was formed that was maintained and expanded by the Tang, Song, Yuan, and Ming dynasties.

The caoyun system reached its maturity during the Tang dynasty. The Grand Canal served as a lifeline to provide the grain needed by the central government and the capital city. The flow of grain was mainly from south to north and from east to west.

The Song dynasty had its capital at Da Liang (now Kaifeng city in Henan Province). The nearby four
Caoyun System ■ Cáoyun xìtōng ■ 漕运系统

rivers—Bian, Huang, Huimin, and Guangji—were connected to support the distribution of grain tribute.

During the Yuan dynasty the caoyun system experienced a shift from shipment by rivers and the canal systems to shipment by sea. Two special caoyun offices were established. One office was responsible for gathering and transporting grain from all over the empire to the city of Zhongruan. The other office was responsible for shipping the grain from Zhongruan to the capital city Dadu. Three thousand ships were built for the grain tribute.

The Grand Canal, connecting the Qiantang, Yangzi, Huai, Huang, and Hai Rivers, was in its grandeur during the Ming dynasty. Starting in 1415 the Ming dynasty ordered that all grain tribute had to go through the inland rivers and canals. As a result, the grain transported via the Grand Canal system accounted for three-quarters of the total. At the time the Grand Canal ran through most of the major cities.

Like so many other Chinese institutions, the grain tribute system entered a period of crisis during the Qing dynasty. The First Opium War (1839–1842) between the Qing empire and Great Britain severely damaged the Grand Canal. The final blow to the caoyun system came from modern transportation by sea and by railway. In 1872 the Ship Bureau was established in Shanghai. In 1911 a railway between Tianjin and Pukou was opened. The grain tribute system officially ended in 1901. The demise of imperial China followed in 1912.

树倒猢狲散
Shù dǎo hú sūn sàn
Chinese world maps have evolved over the years in response to China’s changing views of the world, from the Song dynasty Huayi Tu (Map of China and the Barbarians), a 3-meter-square work, carved in stone, to a map from a 1912 almanac identifying all the places taken from China by foreign imperialism. Maps could be extraordinarily accurate, but often the lines between “China” and what lay beyond were blurred.

Since at least the tenth century, Chinese scholars have produced what might be called world maps. However, until the late nineteenth century, a person contemplating any given world map might well have difficulty determining exactly where China ended and where the rest of the world began. This difficulty arose because large-scale cartographic representations of space during late imperial times in China involved a number of overlapping political, cultural, and geographical images, identified either by dynastic names (Song, Yuan, Ming, and Qing) or by designations such as the Central Cultural Florescence (Zhonghua), the Spiritual Region (Shenzhou), the Nine Regions (Jiuzhou), the Central Kingdom (Zhongguo), the Central Land (Zhongtu), and All under Heaven (Tianxia). The relationship between these conceptions is by no means always evident in traditional Chinese maps.

Many, if not most, premodern Chinese world maps show an abiding concern with the so-called tributary system, which endured as a prominent feature of China’s foreign policy down to the late nineteenth century. This system, which underwent many changes through time, was designed to confirm institutionally the long-standing theory that all of the people living beyond China’s constantly shifting borders, like all those people within them, were in some sense Chinese subjects.

The bringing of tribute to the Chinese emperor by foreign representatives testified to this conceit. As loyal subjects they dated their communications by the Chinese calendar, came to court, presented their local products, and performed all appropriate rituals of submission, including the standard three kneelings and nine prostrations (kowtow). In turn they received a patent of appointment as well as an official seal for correspondence with the Chinese Son of Heaven. They were given lavish presents, offered protection, and often granted privileges of trade at the frontier and at the capital. This assumption of universal overlordship blurred the distinction between maps of China and Chinese maps of the world.

Earliest World Maps

The earliest existing world maps in China date from the Song dynasty (960–1279 CE). One of the most famous examples is the vaguely square-shaped Huayi Tu (Map of China and the Barbarians, 1136), a 3-meter-square work, carved in stone, that boasts about five hundred place names and identifies a dozen or so rivers. The map shows a few foreign lands—notably, Korea and India—but it...
represents more than a hundred different groups of “barbarian” peoples only by written notes in the margins. Several of these notes refer specifically to tributary relationships, past and present.

However, not all Song dynasty renderings of space followed this vague model. Indeed, inscribed on the reverse side of the Huayi Tu is an astonishingly modern-looking work entitled the Yuji Tu (Map of the Tracks of Yu, 1136). It is the earliest existing example of the so-called latticework cartographic grid in China. The outstanding feature of this map, in addition to the near total absence of written commentary, is its extremely accurate depiction of major landforms, including the Shandong Peninsula, as well as China’s two major waterways, the Huang (Yellow) River and the Yangzi (Chang) River. Throughout the remainder of the imperial era, down to 1911, Chinese cartographers continued to produce both kinds of world maps. However, tributary-oriented cultural representations of the Huayi Tu variety vastly outnumbered mathematically accurate ones.

Jesuit missionaries brought sophisticated surveying techniques to China in the seventeenth century, enabling the Qing dynasty (1644–1912) to create extraordinarily accurate maps of the empire for certain political and strategic purposes, but they did not inspire a more general cartographic revolution in China, much less provoke a change in the way the Chinese viewed the world. To be sure, Chinese scholars were not averse to using Western cartographic knowledge selectively. Consider, for example, Cao Junyi’s Tianxia Jiubian Fenye Renji Lucheng Quantu (A Complete Map of Allotted Fields, Human Events and Travel Routes [within and without] the Nine Border Areas under Heaven, 1644). This expansive work acknowledges the existence of Europe, Africa, the Middle East, and India, and gestures toward mathematical accuracy by providing longitudinal lines and degrees, which do not, however, correlate well with specific locations. Yet the Middle East and India are represented primarily by cartouches (ornate or ornamental frames), and Africa, which appears only about one-tenth the size of China, hangs down on the western side of Cao’s map as if it were little more than a protective flank. Europe, tiny and even more marginal, is barely recognizable in the upper northwest portion of the map. Significantly, in his treatment of barbarians, Cao does not differentiate clearly between actual foreign countries and the lands and peoples described in ancient mythical works such as the Shanhai Jing (Classic of Mountains and Seas).
Other Cartographic Traditions

The work of Ma Junliang (flourished c. 1780) shows another effort to integrate radically different cartographic traditions into a single production. Although his Jingban Tianwen Quantu (Capital Edition of a Complete Map [Based on] Astronomy, c. 1790) is dominated by a rectangular Huaiyi Tu–style rendering of the world, with inscriptions that emphasize the process by which barbarian envoys come to China and offer themselves as vassals of the Qing dynasty, it also boasts a seventeenth-century Chinese version of a Jesuit map of the Western Hemisphere and a similarly structured, but more detailed, Chinese map of the Eastern Hemisphere that was first published by Chen Lunjong in his Haiguo Wenjian Lu (Record of Things Heard and Seen in the Maritime Countries) in 1730. An interactive version of Ma’s three-part map with commentary can be found at http://library.rice.edu/services/digital_media_center/projects/jingban-tianwen-quantu.
The rise of Western imperialism during the nineteenth century brought a new level of global awareness to China. Intelligence-gathering efforts during the Anglo-Chinese War of 1839–1842 began the process, and by the end of the Sino-Japanese War (1894–1895), the traditional Chinese worldview had been completely undermined. From this time onward, in elite journals and even popular almanacs and encyclopedias, Chinese readers sought ever more accurate knowledge about other parts of the world, including Japan. As in many other aspects of Chinese life after 1895, the rise of Chinese nationalism—generated by China’s humiliating defeat by the Japanese—brought a revolution in Chinese cartography. One revealing example is a map taken from a popular almanac of 1912, the year the Qing dynasty fell. Although not particularly sophisticated in terms of mathematical cartography, it is instructive because its commentaries identify all the places taken from China by foreign imperialism, including the province of Taiwan and the former tributary states of Korea, the Liuqiu Islands, and Vietnam. Chinese cartography had suddenly become irrevocably global in a radically new and highly nationalistic way.

Cashmere Industry ▶
Cashmere Industry

Shānyángróng gōngyè 山羊绒工业

The northern border steppes of China have been the world’s largest source of cashmere fiber for centuries, but during the past twenty years, the animal hair processing and textile making industry has expanded greatly, so that it now dominates the global market.

The fiber from different varieties of cashmere goats (Capra hircus laniger) has been a major agricultural product of China’s northern border grasslands for centuries. Cashmere—the fine (dehaired) downy undercoat shed by goats living in the high, dry altitudes of Eurasia—lies beneath the coarse outer hair and provides insulation from the cold. This rare, precious natural fiber (often called soft gold or diamond fiber in China) has been prized since Roman times for its lightness, warmth, and softness. The value of the dehaired cashmere is influenced by its fineness in microns, length in millimeters, and color. For centuries it was used exclusively in luxurious fabrics that only royalty could afford: Napoleon III gave cashmere shawls to the empress Eugenie, and Queen Victoria treasured the fabric. In the 1920s, cashmere fabric was made into fashionable clothing by the Parisian designers Coco Chanel and Jean Patou. Cashmere has remained a highly desirable product ever since.

China is considered the home of the finest cashmere and has become the world’s largest cashmere producer. Although agricultural statistics are unreliable, China is thought to produce around 60-65 percent of the world market of 12,000 tons per year. Mongolia is the second-largest producer with about 3,000 tons annually. Other cashmere-producing countries include Iran, Afghanistan, New Zealand, Nepal, Australia, and the United States. The United States is the largest importer of finished cashmere goods, buying three quarters of all finished cashmere knitwear since 2000, according to The Wall Street Journal (Chen 2001).

The cashmere-manufacturing industry developed in the nineteenth century in Scotland, which was recognized for the specialized-weave knit techniques developed there. In the last decade of the twentieth century, cashmere processing and manufacturing increasingly has moved from Europe to the countries of fiber origin, especially China. It takes a Kashmir goat four years to produce enough hair for one sweater. The herders comb the goats by hand every spring; the hair then is sold in bales. Chinese cashmere-down hair comes from goats grazing on the plains of Inner Mongolia, Xinjiang, and the Himalayan Mountain highlands that lead to the Tibetan Plateau—regions surrounding the Gobi Desert. The fibers are locally combed, cleaned, dyed, and spun before being exported or knitted into fabric in northern Chinese mills.

The Cashmere Industry in China

The cashmere industry is divided into three distinct sectors: raw (or greasy) cashmere gathered by herders; processed (or dehaired) cashmere, which is a refined...
combing, cleaning, and sorting process; and finished (or manufactured) cashmere products, including yarns and clothing. Two kilograms of raw cashmere yield one kilogram of processed cashmere.

Before the 1990s most raw cashmere from China was exported (mainly to Europe) for processing and manufacturing. But in the late 1970s, as the Chinese government began moving to a market economy, government officials looked to establish cashmere factories within China. By the 1980s lower-priced cashmere sweaters and other items were being exported, and over the next ten years, the Chinese cashmere industry grew to monopolize the market. Foreign businesspeople were essentially unable to purchase raw cashmere from China. According to the China Chamber of Commerce of Import/Export of Foodstuffs, Native Produce and Animal By-Products (CFNA), there are now more than 2,000 companies in China processing cashmere that use over 90 percent of the world’s raw cashmere (CFNA 2005).

In addition, these businesses process not only domestic cashmere, but also some imported from Mongolia and other countries. After a change in government in 1996, Mongolian authorities lifted a mid-1990s ban on the export of raw cashmere, replacing it with a 30 percent export tax on raw cashmere. However, the tax was poorly implemented, as corrupt senior officials realized that they could make fortunes by selling raw cashmere tax free to Chinese factories. According to a United States Agency for International Development (USAID) May 2005 cashmere study, it was estimated that 40-50 percent of Mongolian raw cashmere is smuggled, duty free, to China. This has allowed China to capture the

Uygur girl and a goat in Kashgar, Xinjiang Uygur Autonomous Region. Cashmere is gleaned by combing the fine down from under the goat’s coarse outer coat. It can take three to four goats per year to make one cashmere sweater. PHOTO BY JOAN LEBOLD COHEN.
Mongolian raw cashmere-export market, depress the Mongolian manufacturing sector, and take control of the world cashmere market.

In 1997, China produced nearly 10,000 tons of raw cashmere and imported over 800 tons of raw cashmere (primarily from Mongolia), exporting no raw cashmere. A total of over 5,000 tons was processed; half was used in the domestic market and half was exported. The half that remained in China was made into finished goods, about a quarter of which went into domestic sales, while the rest was exported. For the past several years, raw cashmere production in China has stabilized to about 12,000 tons (China Daily 2005).

In Inner Mongolia, the number of goats increased tenfold from 2.4 million in 1949 to almost 26 million in 2004 (Osnos 2006). The sharp increase in demand for raw cashmere has had negative environmental consequences on Chinese and Mongolian grasslands where the goats graze. Overgrazing exacerbated by government-imposed limitations on the amount of pastures accessible to the herders has degraded the quality of grasses and caused desertification. As a result, restrictions on the size of goat herds have been implemented in China, although with only limited success (Zukosky 2008).

Cashmere Trade and Future Prospects

In the 1990s, Chinese decollectivization and promotion of private enterprise manufacturing policies led to the rapid expansion of goat herds and to what most experts agree was an oversupply of low-quality cashmere. World prices of raw cashmere dropped from about $60 per kilogram in 1989 to as low as $15 per kilogram in 1998, before climbing somewhat higher. This accounts for the flood of finished cashmere goods at greatly reduced prices, which became available to middle-class consumers on the world market. With the Asian economic crisis of the 1990s, the main market for cashmere goods shifted from Asia and Europe to the United States, which has favorable import regulations.

China’s supply of raw cashmere is expected to remain stable in the next few years, while worldwide demand for cheap cashmere is expected to continue. But with the recent global economic downturn, rises in hair prices in recent years may depress international demand for finished cashmere goods unless attractively low prices are maintained.

Celadon

Qingcí 青瓷

Celadon wares—ceramics with a green or blue-green glaze—are among the oldest glazed ceramics; they during the Shang dynasty (1766–1045 BCE). The green color results from a chemical reaction to small amounts of iron and titanium oxide in the glaze during firing in a kiln.

Celadon is the term for a wide range of ceramics with a pale green or blue-green glaze. The origin of celadon can be traced to the first glazed ceramic objects, which appeared during the Shang dynasty (1766–1045 BCE). The dispersal of celadon across the world indicates a global culture of ceramics that dates to before the era of blue-and-white ware’s dominance in the fourteenth through eighteenth centuries. Indeed, celadon’s global tracks are evidence of the Silk Roads and maritime trade routes linking China with the rest of the world.

Chemically, celadon’s greenish tint results from small amounts of iron and titanium oxide fired in a reducing atmosphere (a kiln atmosphere with a high level of carbon monoxide). Because of the difficulty of maintaining the reducing atmosphere in a kiln during firing, and thus maintaining the chemical reaction, celadon glazes also contain olive and yellow colors.

Conceptually, ancient celadon wares stand in contrast to the class of ceramics known as “porcelain,” a distinction based on body composition, firing temperature range, and degree of vitrification. The term porcelain technically connotes use of petuntse (a form of feldspar occurring only in China) and kaolin, which is a fine, white clay. The combination of these two materials made for a higher firing range. Porcelain stone was first utilized in ceramic making during the tenth century, when potters extracted the raw material in southern China at the porcelain center of Jingdezhen, Jiangxi Province. Porcelain rose in prominence, and the wares were more produced prolific after the late fourteenth century due to the official patronage of Jingdezhen porcelain by the Mongol rulers of the Yuan dynasty (1279–1368), who set up an official administrative unit to govern porcelain one year before they conquered all of China. By contrast, ancient celadon encompasses the stonewares that dominated production before the rise of porcelain production in the tenth century.

Development

The first ceramic glazes appeared in China during the Shang dynasty. The bodies of glazed ceramics were high fired, meaning that their firing temperature was around 1,200° C. In general, they were used mostly in ritual ceremonies. By the eastern Han dynasty (206 BCE–220 CE) the centers of celadon production were located primarily in modern-day Zhejiang and Jiangsu provinces in the lower Yangzi (Chang) River valley. The celadons produced during this time were also fired at around 1,200° C. Zhejiang and Jiangsu provinces correspond roughly with the territories under the control of the Yue and Wu states, thereby explaining the common association of the term Yue ware with types of ancient celadon. During the third and fourth centuries celadon production spread to

© 2009 by Berkshire Publishing Group LLC
Jiangsu, Hubei, Hunan, and Jiangxi provinces. Celadons were produced in southern and northern kilns from the seventh century onward. Their main period of development occurred between 220 CE and 618 CE, encompassing the North and South Dynasties period (220–589 CE) and the Sui dynasty (589–618 CE). Technical development of ancient celadon production culminated during the Tang dynasty (618–907 CE), when they were fired in kilns in the region known then as “Yuezhou” (present-day southern Zhejiang Province). The eighth century brought a resurgence of the greenwares of the Yue kilns, whose term was revived from five hundred years earlier, when it was first used during the Han dynasty. Celadons were the dominant type of wares produced until the late fourteenth century, when they were surpassed by the growing demand for white-bodied porcelains with white-blue glaze made in Jingdezhen, a southern kiln site. This change was also marked by the rise in prominence of blue-and-white wares and a shift in porcelain production centers from the northern kiln sites to southern kiln sites. The Northern Song dynasty (960–1126) brought an increased production of celadon referred to as “Ru ware” and “Guan ware” at kiln sites. After the capital moved to Hangzhou in southern China, celadons—known as “Longquan wares”—were produced at the Longquan kilns, also in southern Zhejiang Province near present-day Wenzhou city. The production of blue-green, thickly glazed, simply shaped celadon stonewares in Longquan County marked another notable point in celadon history.

History of Terminology

In Chinese-language texts, celadon wares are known simply as “greenware,” demonstrating the crucial place of color in celadon’s definition. The comprehensive Chinese-language technical guide to porcelain, entitled Records of Jingdezhen Pottery (Jingdezhen Taolu), dating to the turn of the nineteenth century, refers to celadon wares using the terms for their glaze color, qing and qingci. Translated directly, these two terms mean “greenware.” The Western derivation of the term celadon may have begun in 1171 with a corruption of the name of the sultan Saladin, who made a gift of such celadon wares to the sultan of Damascus, or with the seventeenth-century French play written by Honore Darfe, which featured the shepherd Celadon who...
wore a greenish-gray cloak. Thus, in Western etymological terms, no technical description of the term *celadon* exists. Rather, *celadon* is simply a term whose history comprises descriptive usages.

Ancient celadon has been praised by Chinese writers and collectors in many ways, variously compared with the color of jade or clouds or the sound of light rain. During the Tang dynasty the revival of Yue kilns in southern Zhejiang Province resulted in part from official patronage of celadon wares by the Yue royal families and from the growing popularity of tea drinking as an art and cultural form in China, as well as among other East Asian places. In this cultural context an important document detailing the aesthetics and intricacies of tea drinking reveals the high value of Yue celadon wares at the time. The document, *Classic of Tea* (*Chajing*), written by Lu Yu (733–805 CE), was the first monograph on tea ever written. It comprised ten chapters and praised Yue porcelain for resembling jade and ice. The green color of Yue porcelain, according to Lu Yu, enhanced the green color of the tea itself. About a hundred years later, another poem, written by Xu Yin, a Tang dynasty poet and official active during the late ninth and early tenth centuries, lauded the ability of celadons to enhance the experience of drinking tea. The title of this poem refers to celadons as “secret color” (*mise*):

**The Secret-Colored Bowl as Given to the Emperor**

NEWLY GLAZED IN AUSPICIOUS JADE-LIKE COLORS,

the finished bowl was first given to my lord.

skillfully molded like a clear moon dyed with spring water,

deftly rotated like thin ice holding green clouds,

like a moss-covered ancient bronze mirror present at this occasion,

a tender, dew moistened lotus leaf parted from the river’s edge,

with zhongshan bamboo-leaf wine so recently brewed,

i am weak and unable to withstand such an experience! (Mino and Tsiang 1986, 13)

Evidently, as this poem shows, literati during this period appreciated celadons and compared them with ice, clouds, and jade. The term *mise* (secret color) ware originated during the Wu Yue state of the Five Dynasties period (907–960 CE). According to the *Jingdezheng Taolu* (Records of Jingdezhen Pottery), production of secret-color ware began during the tenth century and ceased at the beginning of the Ming dynasty (1368–1644), and because it existed for specific use at the imperial palace, the ceramics acquired the term *mise*.

**Technological Definition**

The scientific and industrial revolution of the mid-nineteenth century produced new understandings of porcelain. Alexandre Brongniart, a French chemist writing in 1844 as director of the French national ceramic manufacturing center at Sevres, attributed to porcelain these distinctive characteristics: whiteness, translucency, hard paste, not to be scratched by steel, homogeneous, resonant, vitrified, and impermeable to water. In Brongniart’s studies ceramics consisted of three types: earthenware, stoneware, and porcelain. Celadon, according to these types, is stoneware. Stoneware, which dates to the Shang dynasty, was fired at temperatures ranging between 1,100° and 1,270° C. Stoneware has also been called “porcelain ware,” and it includes vitrified objects. By the Han dynasty glazes containing ash content gave rise to the color now subsumed in the definition of celadon, a stoneware of brownish-green or yellowish-green glazes. Also during the early western Han dynasty (206 BCE–220 CE) the word *zi*, an antecedent of the word *ci* (porcelain), was first used to refer to celadons, which were used in burial tombs of elites.

Twentieth-century scientific studies revealed a wide array of chemical elements in various celadon glazes, including calcium, magnesium, soda, phosphorus, titanium, aluminum, silica, and potassium. The degree of translucency or transparency depends on the interaction between the physical properties of light rays and their interaction with heterogeneities of the glaze at the surface and beneath the surface. Approximately 4–6 percent of incidental light rays are reflected and scattered at the outer surface of the glaze. Glazes with elements having a higher atomic number, such as lead, and having a higher mass weight, reflect more light. Glazes of such composition thus appear brighter than feldspathic (relating to or containing feldspar) or alkaline glazes.

The portions of incidental light rays that do pass through the surface are then affected by the internal
structures in the glaze. Bubbles of 0.1 millimeter or smaller in the glaze produce specular reflection, just like the glaze surface. As a result, light bounces off each of the bubbles and produces the glaze’s brightness and luminosity. Undissolved quartz particles absorb light and make the glaze appear matte. Crystals in the glaze result from the long firing and slow cooling at high temperatures. When raw materials are not finely ground and are insufficiently mixed, chemical heterogeneity ensues and creates a chemical composition similar to the crystal. Fine crystals on the order of microns in the glaze refract and scatter the light, thus giving a translucent appearance to the glaze. A rough layer of crystals at times grows at the layer where the glaze touches the clay body, creating the optical effect of a white slip. This layer of white ground reacts with the light and creates internal reflection in the glaze. The combined effect of bubbles, quartz inclusions crystals, and white grounds adds a depth and a luster to celadon glazes that make them appear like jade or green feldspar.

**Major Types of Ancient Celadon**

There are six major classifications of celadon, one of which, Chai ware, survives today only as described in historical texts. The availability of local minerals was a big factor in the makeup and appearance of the various styles.

**Yue Ware**

Yue ware dominated the history of ancient celadon from the Han dynasty to the sixth century CE. Coming to prominence between the third and sixth centuries, the bodies of Yue ware were gray and dense with a thin layer of glazes. Yue ware experienced a revival during the Tang dynasty and was found in Iraq and Iran. Its glazes averaged about 0.2 millimeters and had a high calcium content—up to 60 percent. It was fired mostly in the dragon kilns popular in Zhejiang Province, which caused a rapid cooling cycle. Yue celadons are not as translucent and jade-like as later celadons.

**Longquan Ware**

Longquan celadons, made in a mountainous region in Zhejiang Province southwest of present-day Shanghai close to Fujian Province, were produced during the Southern Song dynasty (1127–1279) and probably are the best known of all celadon types. They are a translucent blue-green color and are often found in the shapes of bowls and jars. They were traded to places such as Southeast Asia, the Philippines, Africa, and the Near East between the twelfth and fourteenth centuries. Thicker than the earlier Yue celadon glazes, Longquan celadon glazes ranged from 0.4 millimeters to 1.7 millimeters thick, thus creating a more translucent visual effect than the earlier Yue.
Celadons. Longquan wares contain small amounts of undissolved clay and quartz, indicating that the Longquan glazes are not as finely grained as Yue ware glazes.

**YAOZHOU WARE**

During the Northern Song dynasty (960–1126) celadon wares known for their molded and incised decorations were produced in Shaanxi Province. They supplanted the white wares and black-glazed wares of the north. Their glaze was gray-green or olive-green, thinly laid over deeply carved or molded bodies. The thickness of the glaze ranged from 0.4 to 0.8 millimeters and was not as unctuous (smooth and greasy in texture or appearance) as that of Longquan wares. The presence of titanium in the raw materials available in the north was responsible for the olive-green hue of the glaze. The titanium increases the brown color when combined with iron in the glazes.

**RU WARE**

Ru ware, another type of Northern Song celadon known for its opaque, unctuous blue glaze on often-undecorated bodies, appeared near the end of the eleventh century. It is extremely rare, with fewer than one hundred complete pieces preserved, mostly in the Percival David collection in London or in the National Palace Museum. Presumably fired for the imperial court, Ru ware was produced only between 1086 and 1106 and was immediately treasured during the twelfth century because of its short production period. Ru ware was probably ordered to replace Ding ware, whose rough, unglazed rim did not please the court. The Ru glaze is so thickly applied that it was likened to layers of fat in the Chinese-language connoisseur texts.

**GUAN WARE**

Guan ware was produced during the Northern and Southern Song dynasties. The Southern Song Guan wares were produced for the imperial court, and thus the term *guan* refers to “official” ware. During the Southern Song dynasty the center of production for Guan ware was right outside Hangzhou in Zhejiang Province, where the court reestablished its capital city after the conquest of the northern provinces by the Mongol Yuan dynasty. Guan glazes are often more than 1 millimeter thick, crackled, and opaque, and the bodies are dark-colored and thin. The bodies are granular because of the presence of find sand in the body composition. Guan wares have a dark mouth (rim) and dark foot, referred to literally as “iron foot” in Chinese-language texts. Modern examinations of Guan shards (pieces or fragments of a brittle substance) reveal that the glaze was often applied by potters in an average of four layers. The high lime content accounts for the crackle. Guan ware is often underfired at a temperature of 1,000° C.

**CHAI WARE**

To date, no archaeological findings can confirm the actual existence of Chai celadon. However, numerous ceramic connoisseurship texts praise Chai ware for being “blue as sky, clear as mirror, thin as paper, and resonant as a musical Bowl made at You-chou kiln, Shaanxi Province, eleventh/twelfth century (Song dynasty). Northern celadon porcelain. Shown at the Ceramic Exhibition, Imperial Palace, Beijing. Photo and caption by Joan Lebold Cohen.
stone” (Hayashiya and Hasebe 1996, 48). Qing dynasty (1644–1912) texts on ceramics note that Chai ceramics were produced for Emperor Chai Shizong (954–959). This elusive but poetically described celadon ware awaits more research, but its mention in texts demonstrates the aesthetic significance of celadon's natural beauty.

**Export History**

The Tang dynasty was an exuberant period of Chinese artistry and foreign contact. Yue celadons were a large part of the export trade between China and Central Asia since the time of the Tang dynasty. Yue celadon wares dating to the ninth century have been found in Southeast Asia, Indonesia, Sri Lanka, the Persian Gulf, and Cairo. The early ninth century brought a large-scale oceangoing trade between the Persian Gulf and China, affecting the trade of celadon ceramics. The first countries to import and even improve upon celadon technology were Korea and Japan. Korea in particular was a major player in the production of celadon. In the eleventh century Korean potters substituted porcelain stone for body clay in their celadon glaze recipes and produced brilliant blue-green celadon wares.Excavated Longquan wares and Guan wares dating to the thirteenth century have been found in Japan and Korea, demonstrating the continued trade of celadon wares through the Yuan dynasty. Longquan wares made during the Song, Yuan, and Ming dynasties were exported to Japan and the Philippines, and the presence of such late greenware ceramics in Japanese museums reveals the widespread appreciation for the simplicity and elegance of celadon glazes.

Tōu liáng huàn zhù
Central Asia-China Relations

Zhōngyà gèguó hé Zhōngguó de wàijiāo guānxi
中亚各国和中国的外交关系

China has complicated relations with the central Asian nations that became independent of the Soviet Union after 1991. Issues include boundary disputes, population growth, economy, nationalism, and separatist movements.

After the Soviet Union collapsed in 1991 China faced the challenge of managing bilateral relations with the newly independent nations of central Asia. The independence of these nations worsened long-simmering ethnic unrest in China’s Xinjiang Autonomous Region, which borders several central Asian nations. China, after establishing relations with the central Asian nations in early 1992, signed with them more than twenty agreements on boundaries and cultural and economic cooperation within a short period.

Unequal Treaties

The boundary between China and central Asia was originally established by so-called unequal treaties—the 1860 Treaty of Beijing, the 1864 Protocol on the Northwest Boundary, the 1881 Sino-Russian Treaty of Ili, and the 1884 Sino-Russian Treaty of Kashgar. According to China, these treaties gave czarist Russia 440,000 square kilometers of land at the expense of China. After the central Asian nations became independent, China was willing to accept the unequal treaties as the basis for new boundary agreements.

After several years of negotiation, on 4 July 1996 China reached a boundary agreement with Kyrgyzstan. Kyrgyzstan and China have since reached agreements to open new border crossings and to build a railway linking the two nations. On 4 July 1998 leaders of China and Kazakhstan signed a boundary treaty that settled lingering questions about the 1,700-kilometer Sino-Kazakh boundary.

China and Tajikistan settled their historically complicated boundary dispute in 2002. China claimed that Russia violated the 1884 Sino-Russian Kashgar Boundary Treaty in 1892 and occupied 28,000 square kilometers of Chinese territory in the Pamir Mountains and that the boundary remained undefined. Nevertheless, the two nations negotiated many agreements, including one to open a road connecting China and Tajikistan to ease border trade before settling the boundary dispute. In the final settlement, China received approximately 1,000 square kilometers of its original claim.

Demographic and Economic Threat

The central Asian nations view China as a demographic and economic threat. One of their concerns is China’s dramatic increase in population. Central Asia, with its vast territory and rich natural resources, is a logical area for China to covet. More than 300,000 Chinese have settled in central Asia, and that number may increase to 500,000 by the end of 2010. In fact, officials in Kazakhstan...
worry that if the flood of Chinese coming into their country continues, Chinese could overwhelm Kazakhstan by 2020. In addition, Chinese traders have bought considerable amounts of real estate in Kyrgyzstan.

For its part China is apprehensive about instability along its border. After a summit in Shanghai, on 26 April 1996 Russia, Kyrgyzstan, Kazakhstan, and Tajikistan signed an agreement with China concerning confidence-building measures along the border. On 24 April 1997 the nations agreed to withdraw military forces 100 kilometers along the 3,500-kilometer boundary. A third agreement, signed on 3 July 1998, stressed cooperation to lessen ethnic unrest in the region. Each nation promised to fight arms smuggling and not to allow its territory to be used to undermine the national sovereignty, social order, and security of any of the five nations.

Nationalism and Separatist Movement

Ethnic unrest in Xinjiang Autonomous Region has been a major concern for China since the independence of the central Asian nations. A continuing source of stress in China–central Asia relations has been the sensitive subjects of pan-Turkic nationalism and the Xinjiang separatist movement. China historically has struggled to maintain central government control over that region. Recent issues have been Russian and Soviet intrigue and local independence movements. In 1944 the short-lived East Turkistan Republic was established in what is now Xinjiang Autonomous Region; it had a national anthem and a national flag—a white crescent and star against a blue background. The Uyghurs of Xinjiang, led by Islamic scholars, wanted a homeland free of Chinese influence. China in 1962 put down a revolt by thousands of Kazakhs, who then fled across the border to Soviet Kazakhstan. China now feels that the simmering independence movements in Xinjiang Autonomous Region are the main threat to stability in western China.

A central point in most discussions between China and central Asian nations is a commitment not to support separatist movements. Kyrgyzstan and Kazakhstan, with 80,000 and 200,000 Uygurs, respectively, have agreed to suppress such movements. Several separatist movements have migrated from Kazakhstan to Turkey, and Kyrgyzstan has suppressed organization of an ethnic Uyghur political party. The Uygur nationalist groups that continue to operate in central Asian states remain a major source of tension in their relations with China.

Nations that have fundamentalist Islamic orientations are a factor in fomenting ethnic unrest in the region.
For example, the Jamaat-i-Islami, based in Pakistan, has encouraged Islamic activism in Xinjiang Autonomous Region, as have other Islamist movements such as the Taliban (when it was in power in Afghanistan). Uygurs receive religious training in Pakistan, and Islamic and Afghan militants have smuggled arms into China. The number of Islamic schools in China has increased rapidly; in 1997 the government shut down as many as three hundred “illegal” schools. Some neighborhood mosques have become the focus of anti-Chinese activity. China has clamped down on what it considers to be illegal religious activities and has closed many mosques.

The increase in ethnic unrest and pro-independence demonstrations and other activities has deep religious and historical roots and will continue for the foreseeable future. Many leaders are not simply religious fanatics but rather are pan-Turkic nationalists. Support for their movement comes from neighboring Turkic-speaking countries. In spite of a pledge by Kazakhstan and Kyrgyzstan not to support the Xinjiang separatist movement, supporters of the movement openly operate from these two countries. Uygurs living in Turkey also support the movement. Anti-Chinese colonialism and pan-Turkic nationalism are important sources of the unrest. Uygurs are attempting to preserve their cultural identity and to resist the large influx of Chinese settlers into their region.

**Increasing Border Trade**

During the 1990s central Asia quickly became an important part of China's economic attention. Border trade is a vital part of growing economic relations. In 1989 Xinjiang Autonomous Region's trade with Soviet central Asia totaled only $118.5 million. In 1995 total trade between China and central Asia was estimated at $718 million, of which $500 million was border trade. China since 1991 has become the second-largest trading partner for central Asian nations, significantly displacing Russian influence in the region. Kazakhstan's major trading partner is now China, and one-quarter of Kyrgyzstan's foreign trade is with China. As of 2008 trade with China (including oil exports) has increased to account for 60 percent of the region's foreign trade.

The development of gas and oil is an area of vital strategic economic cooperation. China and Turkmenistan in 1994 signed an agreement to build a Turkmenistan-China-Japan gas pipeline. In 1997 China won the bid to develop Kazakhstan's Uzen oil field and to build a 3,000-kilometer oil pipeline from Kazakhstan's Caspian oil fields at Tengiz to Xinjiang Autonomous Region and then to China's east coast. China also signed agreements with Kazakhstan to develop the Aktyubinsk oil fields along the Russian-Kazakh border. China's total investment in developing oil resources in Kazakhstan is estimated at $9.7 billion. That is equivalent to 50 percent of Kazakhstan's gross national product. Such agreements indicate that China and central Asia are developing an important economic and strategic relationship. China not only is seeking to ensure its energy security for the future but also is seeking to shift the focus of central Asia's global vision toward China and away from Turkey and Russia.

Changling Mausoleum

The Changling Mausoleum is the resting place of the Ming Yongle Emperor (reigned 1403–24), whose given name was Zhu Di and whose posthumous title is Chengzu. At 120,000 square meters, it is one of the grandest and certainly the best preserved of all of the Thirteen Ming Tombs (shisan ling) that lie roughly 45 kilometers north of Beijing in a valley below the Tianshou Mountains.

Emperor Ming Yongle, or Zhu Di as he was known at birth, was an emperor of usurpation. He gained the title after a four-year war with his nephew, whom the first Ming emperor had chosen for the throne. Like the construction of the Forbidden City in Beijing, which Zhu Di designated the Ming capital after his ascension to the throne, the building of the Changling Mausoleum was yet another project to legitimate Zhu Di as the true successor to the Ming emperorship, and Beijing as the true capital of the Ming Empire.

The construction of Changling began in 1409. By 1413, the underground tomb was completed. The exact structure of the Changling tomb is not known, but it is likely that it is similar in construction to the excavated Dingling tomb. Upon completion of the tomb, Zhu Di ordered the body of his empress Xu, which was being kept in Nanjing, to be buried in the tomb chamber. The tomb was covered with a large mound, or tumulus, which remains undisturbed today.
Over the next fourteen years, workers continued to build the complex of ceremonial halls leading to the Changling tumulus. The entire complex runs roughly from south to north, ending at the tumulus. It is approached almost directly from the Spirit Path (shen dao) upon which all emperors living or dead must be carried as they approach the Thirteen Tombs. Following a slightly winding road around 5 kilometers northward from the exit of the Spirit Path, one reaches the entrance to Changling, a standard ceremonial arched gateway with three entrances. The emperor would pass through the central entrance, while nobles passed through the right entrance and officials through the left. The design of the Changling is quite similar in ways to that of the Forbidden City, also constructed under the Yongle reign.

Built upon a hillside, the ceremonial path through the tomb complex leads northward and upward. Beyond the entrance and to the right lies a double-eaved wooden pavilion erected in 1542, housing a stele carried by a mythical animal with a tortoise body symbolizing longevity and with a coiling dragon on top. During the Ming, the stele contained no epitaph, but during the Qing it was engraved with imperial edicts and poems of Qing emperors, who sought to legitimize their own succession by honoring the Ming imperial tombs.

The imperial pathway then passes through the Ling’en Gate, an open hall with three entranceways. A set of stairs leads to the gate on both sides. Upon the central stairway over which the living emperor passed as he paid homage to his ancestors is a marble carving showing water, deer,
mountains, and two dragons flying in clouds, symbolizing imperial power or perhaps the soul of the emperor in the afterlife. Two sacrificial burners lie on either side of the north exit of the gate, which faces into a large square section containing the Ling’en ceremonial hall. These burners were meant for silk, money, and other combustible items that could be sent on to the afterlife by burning them.

This Ling’en hall is a uniquely preserved feature of Changling and by far its most distinguished. It is the second largest hall of its type that still survives from the Ming dynasty. The hall is elevated and is approached by a set of stairs with marble balustrades. Like the halls of the Forbidden City, there are three tiers, the lower symbolizing hell, the middle earth, and the higher heaven. A marble pathway built for the emperor lies upon the middle stair.

The hall is covered by a large double-eaved rooftop, decorated with images of dragons and other mythical creatures. Supporting the roof are sixty columns constructed out of nanmu, a fragrant cedar indigenous to southwestern China. It took about five years on average for each tree to be transported to the northern tomb, which helps to explain why it took workers another four years after the emperor’s death to complete this building and the tomb complex. During the Ming dynasty, the Yongle emperor’s spirit tablet was kept in the hall, and during ceremonies such as Yongle’s birthday, the living emperor, nobles, and officials would give food and other offerings to the spirit tablets of the emperor and empress.

Having passed through the Ling’en hall, one enters through a simple gateway known as a “stargazing gate” to

**Altar in front of the stele tower, Tomb of Emperor Zhu Di (the Yongle emperor).** Vessels used for offerings were usually made of lacquer, metal, or ceramic, but here they have been fashioned for posterity out of marble. The central vessel simulates a censer (incense burner) in a ding tripod shape. The sculptor has formalized the vaporous emissions, like a great conical hat. A dragon resides in this cloud. Photo by Joan Lebold Cohen.
the Soul Tower, a pavilion built atop a tall stone edifice containing a stele commemorating the Yongle Emperor. Before the Soul Tower is a marble altar containing five ceremonial objects—the last step in the ritual process of obeisance to the spirit of the emperor. A passageway leads through the fortification and around the other side to the Soul Tower. Behind the Soul Tower lies the tumulus, which is still undisturbed.

The Changling Mausoleum provided the basic blueprint for the construction of the subsequent twelve surrounding Ming tombs, though they all differ in detail. Some scholars speculate that were it not for the construction of Changling, Beijing may not have remained the imperial capital, as it was vulnerable to attacks from the Mongols. Moreover, in 1421, the year that Zhu Di finally led the imperial retinue to the new capital from Nanjing, some palaces in the newly built Forbidden City were struck by lightning and burnt down. While some officials saw this as a bad omen and suggested moving back to Nanjing, others remarked that the imperial tomb was already in the area of Beijing, thus justifying remaining there despite the ill omen. In this sense, Changling was the anchor that held the capital in Beijing.

One of the reasons that the tomb complex is so well preserved is that Mao Zedong paid a visit to Changling in 1954, thereby consecrating it as a historical site and preserving it from the ravages of the Cultural Revolution.

CHEN Cheng
Chén Chéng 陈诚
1898–1965  Military leader under Chiang Kai-shek

Chen Cheng was Chinese Nationalist Party leader Chiang Kai-shek’s right-hand man during the early years of the Republic of China (1912–1949) and later, under Chiang, was premier of the Guomindang (Kuomintang) government-in-exile in Taiwan.

Chen Cheng was born in Zhejiang Province. He attended Whampoa (黃浦 Huangpu) Military Academy, where he met Chinese Nationalist Party (Guomindang) leader Chiang Kai-shek, whom he eventually followed into exile. During the War of Resistance against Japan (1937–1945) he was China’s minister of war. Later he was promoted to a full general, chief of general staff, and commander-in-chief of the Chinese navy.

After Chiang’s defeat in the Civil War between the Nationalists and Communists (1945–1949), Chen fled to Taiwan with Chiang Kai-shek and became governor of Taiwan (1949–1950). He also served nonconsecutive terms as premier of Chiang’s government-in-exile in Taiwan from 1950 to 1954 and from 1958 to 1963. Chen’s major

Chen Cheng, Chiang Kai-shek’s “right-hand man,” at a tree planting ceremony in Yilan County, 1954. By instituting universal primary education and expanding opportunities for secondary and college education, Chen promoted strong investment in “human capital.”
accomplishments in Taiwan included land reform policies, which had two major components: (1) He reduced rents by 37.5 percent on crop-producing land, and (2) he sold public land held by the ROC government to tenant farmers. In addition, Chen implemented a massive program to provide farmers with new technology, obtained through U.S. assistance, to maximize production. Chen implemented the so-called import substitution policy, establishing strong government control over many kinds of imports to protect the domestic market from foreign competition, while saving foreign exchange for products that Chen thought could be used to promote Taiwan’s industrialization. Furthermore, he promoted strong investment in “human capital” by instituting universal primary education and expanding opportunities for secondary and college education.

Chen Duxiu 陈独秀
1879–1942  Chinese Communist Party founder

Chen Duxiu 陈独秀, founder of the Chinese Communist Party and a leader of the New Culture Movement (c. 1915–1923), was a lifelong rebel who fought corrupt political practice, first against the Qing dynasty, then against the warlord Yuan Shikai 袁世凯, and finally against the ruling Guomindang 国民党 (Nationalist Party led by Chiang Kai-shek 蒋介石).

Chen Duxiu was a classically trained scholar-turned-rebel who published the famous journal, *New Youth (Xin Qingnian)*, which persuaded an entire generation of young intellectuals to repudiate their own culture and to embrace a Western scientific frame of mind and a democratic political outlook. At the same time, he and his fellow intellectual Hu Shi 胡适 succeeded in bringing about the vernacular movement, or the change from writing in a classical to a colloquial syntax. In 1920 he established the Shanghai Marxist Study Society, which was the precursor of the Chinese Communist Party. He was expelled from the party in 1929.

Chen was born in Huai-ning (now Anqing), Anhui Province. Classically educated, he placed first in the first-level civil service exam at age seventeen. He failed the next level of exam but wrote *A Treatise on the Defense of the Yangzi River* — a reflection of his growing patriotism — a year later. He studied in Japan on five occasions and joined the Youth Society, in 1902. He was expelled from Japan in 1903 for cutting off the queue (a braid of hair usually worn hanging at the back of the head) of a Chinese official — an
act that symbolized his hatred for the ineffective and corrupt Qing dynasty (1644–1912). He returned home and formed the Anhui Patriotic Society. In 1903, with the closing of the revolutionary newspaper Subao, Chen and his friends edited its replacement, The Citizen's Daily (Guomin riribao). When this enterprise fell apart due to internal dissent, Chen returned to his home province and published the Anhui Vernacular Paper in 1904. For a brief period he also learned to make bombs with the Shanghai Assassination Squad established by Cai Yuanpei. Chen formed an anti-Manchu organization, the Yuewanghui, in 1905 and was implicated in Xu Xilin’s assassination of Governor-General Enming.

After the 1911 revolution, which established Republican China (1912–1949), Chen briefly served as secretary-general of the Anhui provisional government and helped to develop a military strategy to overthrow President Yuan Shikai. When the attempt failed, Chen escaped to Japan and edited Tiger magazine with Zhang Shizhao in 1914. He returned to Shanghai in 1915 and founded Youth magazine, later renamed New Youth. Chen became the dean of the School of Letters at Beijing University in 1917 at the invitation of Cai Yuanpei, then chancellor of the university. Chen galvanized a generation of young people with his eloquent essay, “Call to Youth” (1915) in which he urged the young to adopt six new attitudes: to be self-directed, progressive, proactive, global, practical, and scientific. He hailed French civilization for bestowing upon humanity three gifts: science, democracy, and socialism. Chen and Professor Hu Shi played a leading role in transforming written Chinese from a classical form to one reflecting the spoken language, a development of enormous importance. Disillusioned by the clash between Western powers in World War I and the outcome of the Treaty of Versailles, and inspired by the Bolshevik Revolution in Russia, Chen turned to Marxism as a means to building a strong, self-sufficient China. Aided by Russian Comintern (the Communist International established in 1919 and dissolved in 1943) agent Gregori Voitinsky, Chen founded the first Communist cell in Shanghai in the summer of 1920 and was elected secretary-general of the Chinese Communist Party (CCP) at its first congress on 23 July 1921. In 1920 Chen also served briefly as education secretary for the Guangzhou (Canton) warlord Chen Jiongming. As party secretary from 1921 to 1927 Chen Duxiu repeatedly protested Moscow’s contradictory directive to join the Chinese Nationalist Party (Guomindang) and usurp its power from within. He was blamed by the CCP for carrying out Comintern orders to conduct doomed labor and peasant uprisings in the face of overwhelming opposition by the warlords and by General Chiang Kai-shek. He resigned as party secretary on 15 July 1923 and was expelled from the CCP on 15 November 1929 for failing to follow Comintern directives, for being antiparty, and for thinking like a Trotskyite (an adherent of Russian Communist leader Leon Trotsky). Chen joined the Chinese Trotskyites for a brief period. He was jailed by Chiang Kai-shek from 1932 to 1937. In prison he pursued his scholarly interest in phonetics and philology (the study of literature and of disciplines relevant to literature or to language as used in literature). He died destitute five years after his release from prison.

Film director Chen Kaige became the first member of the so-called Fifth Generation of Chinese film directors to win international success when he made *Yellow Earth* in 1984. His latest film is *Forever Enthralled* (2008).

With his film *Yellow Earth* (1984), Chen Kaige became the first member of the so-called Fifth Generation of Chinese film directors to attain international success. The Fifth Generation, whose members were graduates of the first class of the reopened Beijing Film Academy after the Cultural Revolution (1966–1976), came of age after the death of Chinese Communist Party leader Mao Zedong (1893–1976) and reacted against the didacticism and melodrama of China’s film tradition.

*Yellow Earth* contains beautiful visuals similar to Chinese paintings. Deceptively simple with minimal action and dialogue, the film is a multilayered examination of the effect of China’s feudal culture and modern revolution on the peasants.

Chen’s next film to gain international fame was *Farewell My Concubine* (1993). This film is set in the Beijing Opera of the twentieth century and deals with the betrayal of...
love and art. It won the Palme d’Or prize at the Cannes Film Festival and other awards. Chen’s 1999 film, *The Emperor and the Assassin*, is a historical epic about Qin dynasty emperor Shi Huangdi or Ying Zheng, who unified China in the third century BCE.

In the 1980s and 1990s Chen and other filmmakers achieved success in international film festivals and art house markets and looked overseas for financing for their projects. His 2005 film *The Promise* was edited and adapted for North American audiences and released in May 2006; his most recent film *Forever Enthralled* (2008) is a biographical film based on the life of Mei Lanfang, the male Beijing Opera star famous for playing women’s roles.

欲盖弥彰

Yù gài mí zhāng
Chen Shui-bian was the second Taiwanese native to be elected president of Taiwan, winning his first term in 2000 and his second term in 2004. (Lee Teng-hui was the first native-born Taiwanese elected president.) Chen's second term ended in May 2008, and by law he was not permitted to run for a third term.

Chen Shui-bian was born into a poor family in Tainan, Taiwan, on 18 February 1951. He graduated from National Taiwan University, majoring in law, in 1974. He began his law practice in 1976, gaining prominence in 1980 when he defended Annette Lu (his second-term vice president) against charges that she helped organize an antigovernment political protest that became violent. The protest, known as the "Kaohsiung Incident" after the city in which it took place in December 1979, resulted in alleged injuries to 181 police officers, although no protesters were injured. The government, dominated by the Guomindang (Kuomintang, Chinese Nationalist Party), held a trial in March 1980 and sentenced the organizers to jail. Chen himself was convicted of slander and forced to serve a short jail sentence.

Chen Shui-bian, former president of Taiwan, and Congressman Gary Ackerman of New York. Chen's political career began in 1981 when he was elected to the Taipei City Council, where he served until 1985 as a non-Kuomintang member. Soon Chen became prominent within the Democratic Progressive Party, rising to become president in 2000.
Chen's political career began in 1981 when he was elected to the Taipei City Council, where he served until 1985 as an independent (that is, non-Guomindang) member. Soon Chen became prominent within the Democratic Progressive Party (DPP), serving most notably as a member of the Standing Committee of the Central Committee, 1987–1989; DPP Caucus member, 1990–1993; and convener of the DPP’s National Defense Committee, 1992–1994. He was also elected to Taiwan’s Legislative Yuan, 1989–1994, during which time he chaired the Formosa Foundation (1990).

In 1994 Chen was elected mayor of Taipei, defeating the Guomindang incumbent Huang Ta-chou. Chen lost his reelection bid in 1998 to Ma Ying-jeou of the Guomindang. However, this loss afforded Chen the time to prepare his run for the presidency in 2000, when he won with less than 40 percent of the votes cast after the Guomindang split into two parties, thus dividing the electorate three ways. Chen was the least known of the candidates and had not been expected to win. In 2004 Chen was reelected president with the help of former President Lee Teng-hui’s Taiwan Solidarity Union, although his razor-thin margin of victory generated some controversy. Just hours before votes were to be cast, Chen and vice presidential candidate Annette Lu were allegedly shot at by a would-be assassin using a “home-made” bullet. Some in the opposition implied that the shooting had been staged to generate sympathy and called for a recount but ultimately were unsuccessful in challenging Chen’s reelection. Later that year, however, Chen’s DPP suffered a setback in the Legislative Yuan elections.

During Chen’s terms as president he faced accusations that his government mismanaged Taiwan’s economy. Even his wife, Wu Shu-chen, and their son-in-law faced legal charges for corruption. Chen Shuibian went on trial in March 2009 on charges of embezzling 104m New Taiwan dollars (£2m) from a special presidential fund, receiving bribes, and laundering money.

Despite these controversies Chen has hoped that history will view him more kindly as the “founding father” of an independent Taiwan for maintaining steadfast, public opposition to Taiwan’s reunification with the Chinese mainland.

Chen Yifei was one of the most prolific and successful artists in twentieth-century China. His paintings were well received by audiences in both Europe and the United States. He was also one of a small number of Chinese painters who was able to sell the majority of his paintings in his lifetime and to demand high prices.

Chen Yifei was born in Zhenhai, Zhejiang Province, and initially trained as an oil painter specializing in the realistic oil painting technique at Shanghai College of Art (or Shanghai Painting Academy) in the 1960s. He received his master of fine arts degree from Hunter College in New York City in the 1980s. At the Shanghai Academy of Art, his formal training was in Russian social realism; however, artists of the Baroque era and Romantic artists (such as the French painter Eugene Delacroix) may have influenced his composition and his use of light and shadow. He was commissioned by the Chinese Communist Party to design inspiration propaganda for the Military Museum in Beijing in 1977. He responded with the ambitious oil painting, Overturning the Dynasty of Chiang Kai-shek, which was completed in collaboration with Wei Jingshan (b. 1943). Another masterpiece, Looking at History from My Space (1979), which has been exhibited in the United States, displays a self-assurance and profound reflection of social realism and patriotic youth. Such views of historical events are characteristic of Chen’s works before 1980.

From 1981 to 1992 Chen resided in and traveled in the United States and Europe and expressed his view of China in a sentimental fashion. His paintings during this time often took as their focus Chinese women figures with elaborate traditional Chinese costumes. A typical example is Lingering Melodies from the Xunyang River (1991), which satisfied Western appetites with the “exoticism” and “Orientalism” of its subjects. From 1993 until 2005 Chen frequently visited China and expanded his artistic talents into industrial endeavors, including films and fashion designs. The first of his films was entitled Haishang jiumeng (Old Dreams of Shanghai, 1993). He died during the filming of his fifth film, Lifa shi (The Barber), in 2005. During his early film career Chen established a modeling agency to recruit and train actresses for his films. Some of these actresses later became models for his oil paintings. His modeling agency and his later work as a fashion designer grew out of his ambitions in the film industry. Through his various endeavors Chen intended to cultivate his actresses in bourgeois taste and manners. In 1997 Chen established his first logo and retail fashion store in Shanghai; today more than 170 retail stores in China bear his logo. During this productive post-1992 period he continued to execute realistic oil paintings. Women figures, dressed in traditional Chinese costumes, remained the focus of his oil paintings. In this last phase of his artistic career he also produced portraits of Chinese ethnic minorities, including Tibetans.

Chen Yifei’s early oil paintings were “academic” and “idealistic” in light of the motivation that sustains his artistic reputation in the modern era. However, such labels minimize the sophistication and depth of his early...
work. His choices of exotic subjects such as fashionable Chinese women were successful in terms of bringing him fame and fortune, but the “commercial” success of these works is controversial in terms of his deeper motivations and apparently compromised ideals. Chen abandoned his idealistic and patriotic view of China and found success in culturally decorative and visually appealing subjects. Furthermore, even though he focused on ethnic minorities in some of his later paintings, this choice comes across as simply a response to demands to produce a trendy cultural product. Although Chen consistently obtained supreme realistic techniques in oil painting, the subject matter and themes in later works failed to match his early monumental pieces in composition, sophistication, complexity, and depth of ideas and ideals.

CHEN Yun
Chén Yún 陈云
1905–1995  Early Communist leader

Chen Yun, one of the most influential of China’s early Communist leaders, occupied a central place in the inner circle of leadership for much of the history of the Chinese Communist Party (CCP). He served on the Central Committee for 56 years and on the Politburo for over four decades—longer than Deng Xiaoping—but was never a contender for the party’s top post.

Considered to be one of China’s “eight immortals,” a group of Chinese Communist Party (CCP) patriarchs who held significant power after the death of Mao Zedong in 1976, Chen Yun was perhaps most famous for his theory of the “bird-cage economy.” He held that China’s market should be allowed to perform like a bird in a cage. The cage should not be so small that the bird cannot fly, but the bird should remain within the confines of a cage, lest it fly away.

Born in Qingpu near Shanghai on 13 June 1905, Chen worked as a typesetter in Shanghai before joining the CCP in 1925. He participated in the early part of the Long March before being sent to Moscow for training. After returning to China, Chen emerged as a key economic thinker and ideological theorist, especially during the 1942 Rectification Campaign. After the Communists came to power in 1949, Chen became the head economic planner, successfully managing the first phase of industrialization and ending runaway inflation. His economic policies, heavily based on the Soviet model of industrialization, provided the basis for economic development into the mid-1950s. But when the Chinese leadership decided to abandon the Soviet model to follow a more Chinese path to socialism, conflict between Mao and Chen began to emerge.

Chen rejected Mao’s view that economic development could be attained through the revolutionary enthusiasm of the masses. Instead, Chen argued for slower and more stable economic growth, saying that the market, rather than mass political mobilization, should play a role in boosting agricultural production. Mao’s view won out, however, in 1956 when he pushed through a plan for collectivization of agriculture and rapid industrialization that eventually led to the Great Leap Forward and the deaths of 40 million Chinese from starvation between 1958 and 1961.

Following the Great Leap Forward, Chen toured the countryside to assess the movement’s failures and later found support for his criticisms from key leaders such as Deng Xiaoping, Liu Shaoqi, and Zhou Enlai. By 1962, Chen’s economic theories were again accepted, and he succeeded in achieving a measure of economic recovery. But his policies were set aside once more in 1966 at the onset of the Cultural Revolution (1966–1976). His political survival skills served him well, however, as he managed to hold on to his seat on the Central Committee while many other leaders, including Deng, suffered political persecution.

The Cultural Revolution caused significant damage to the Chinese economy, and in 1978 Chen was called on to put things right. He helped bring about the return of
Deng, and for a short time the two developed a partnership that sought to privatize some land for farmers and allow limited foreign investment—ideas that later formed the core of the Deng-era reforms. However, the two came to disagree over the speed and scope of reform. By 1984, Chen had become one of Deng’s harshest critics as the economy moved further from central control and more toward open markets.

In 1987, Chen “retired” from his official post on the Central Committee but remained highly influential behind the scenes. After the Tiananmen crackdown in June 1989, he came out in support of Deng and the military. But he remained a constant critic of economic reforms into the 1990s, faulting the reformers for producing unbalanced regional growth and for failing to balance the budget. By the time of his death on 10 April 1995, he held little political influence. His economic theories, once considered to be advanced, were now seen as hard-line and conservative. China’s economy had already flown too far toward open markets to be brought back into the “bird cage.”

Further Reading
Chen Ziang helped to instill in early Tang dynasty poetry the need for meaningful content. The past as perfect and the present as flawed were important themes in his poetry.

The influence that Chen Ziang exerted in the development of early Tang dynasty (618–907 CE) poetry is remarkable because he took it from the fashionable concern for ornate style and imbued it with the need for meaningful content. Being a scholar-official, he served the royal court in various capacities while exerting great influence with his writing, both poetry and prose. His entire life was spent serving Empress Wu, the first and only emperor in name of China.

Chen drew his inspiration from the past and looked to the aesthetics of the Han dynasty (206 BCE–220 CE) to inform and guide his own literary production. Thus, his idea of change was peculiar in that it involved not the invention of new modes of artistic endeavor but rather the restoration of what had existed before and what he felt had slowly been eroded and squandered by the pursuit of an excessively ornamental style in his own day. During the Wei and Han periods he found writing to be concerned with its proper subject: content. He wished to see literature involved not as a means of entertainment but rather as a didactic tool to better the individual and society. Chen’s desire to establish once again ancient modes of literary expression stemmed from his own Confucian ideas that favored simplicity over vain linguistic bedazzlements, shortcomings that he ascribed to courtly decadence. Thus, he promoted the recovering of ancient wisdom that may become a guide for the present. Such an outlook made Chen into an important literary theorist whose concepts would, in time, come to be highly influential on the writers of the later Tang period who adopted his ideal of simplicity and economy of expression over impressive yet meaningless ornamentation.

Some scholars feel that Chen used his poetry to write cryptic attacks on the rule of Empress Wu, especially his noted collection of thirty-eight poems known as the Ganyu. However, it is difficult to imagine that Chen would cast his words in such an arcane fashion because that would defeat his own aesthetic of gaining a mode of expression entirely free of artificial contrivances. Rather, it is more fruitful to view Chen as a thinker concerned with intellectual reforms that would in turn influence the way society functioned and governed itself, which would also be in keeping with his Confucian ideals, which advocated a concern for the here-and-now rather than the hereafter.

The past as perfect and the present as flawed became important themes in the prose and poetry of Chen. Because he cast the past as idealized history, the imitation of which will liberate the present, he sought examples that would serve this end. And yet his approach was never heavy-handed because he also recognized that his aesthetic may well have been futile in that the past forever remains elusive and cannot be fully recovered. In a famous poem, “Song on Ascending the Tower at Yu-chou,” Chen describes this dilemma by stating that the past lies before him in that the ancients are his guides, and the future is behind him in that it consists of people yet unborn.
and therefore unknown. Yet, he is able to see neither the ancients nor the generations yet to come. This realization leads him to a curious existential sadness.

Chen supposedly died in prison, where he had been sent because of his open criticisms of the government. However, his death is a source of contention, and the truth of his last days is unclear.

**Further Reading**

Chengdu is the modern, busy capital city of Sichuan Province in south central China. It is a key economic area, a major transportation hub, an important communication center, and the gateway to the Wolong Nature Reserve, the natural habitat of the giant panda. It also became widely known in 2008: the epicenter of the deadly Sichuan earthquake was a mere 80 kilometers away.

Chengdu, the capital of Sichuan Province in south-central China, lies on the western edge of the Sichuan Basin. The climate of the area is mild, with long summers and short winters but quite humid and cloudy all year round. Chengdu, in fact, has fewer sunny days per year than London has.

Sichuan Province is rich in natural resources and fertile farmland. The Min and Tuo rivers, two branches of the Yangzi (Chang) River, supply an irrigation area of more than 700 square kilometers (270 square miles) and help supply Chengdu with abundant hydroelectric power.

Chengdu covers a total area of 12,300 square kilometers (4,749 square miles), which is quite large for a city (again, for comparison: London, a large city by any standard, covers 2,263 square kilometers). In China’s administrative structure, Chengdu is one of sixteen subprovincial cities, an entity that controls other cities and counties in its region. A subprovincial city is governed by its province but independently manages its own economy and legal structure. Its status is below that of a municipality, which does not belong to any province, but above that of a prefecture-level city, which is governed by its province. Chengdu’s government controls nine districts, four cities, and six counties.

Greater Chengdu has a population of more than 11 million people. The majority of the people are of the Han ethnic group. Chengdu residents have a reputation for being relaxed and fun loving. The city has more bars and teahouses than Shanghai has, even though Shanghai has twice the number of people. The local cuisine is the hot and spicy Sichuan style, with such popular dishes as dan dan noodles and the many varieties of the hotpot.

Chengdu was founded in the third century BCE by the ancient state of Qin, and benefited from one of the oldest and best Chinese irrigation systems constructed in the same century with water from the Min River, which is still in effective use today. It has remained a prosperous city through the centuries and gained a position as one of the most important trade centers of the empire. Traders in Chengdu were the first to use paper money, in the tenth century. Chengdu also became the center of the silk brocade manufacturing industry.

The 1937–1945 Japanese occupation of eastern China gave Chengdu an unexpected boost because the Chinese Nationalist Party (Guomindang) established its capital in Sichuan and moved important industries to the city.

Today Chengdu has a wide variety of industries. Heavy machinery, aluminum plants, chemical plants, and especially electronics are important. In addition,
the textile industry—manufacturing cotton, wool, silk, and satin products—is a major part of the economy. In recent years the city has become a major regional financial center. The city also has a number of universities and other higher education institutions, including Sichuan University and a college of traditional Chinese medicine.

Chengdu received international attention on 12 May 2008 when the deadly Sichuan (or Wenchuan) earthquake struck the region, killing more than 69,000 people and injuring a further 374,000. The initial quake measured 7.9 on the Richter scale, and there were as many as 21,000 aftershocks for several weeks after. The epicenter of the earthquake was 80 kilometers (50 miles) northwest of Chengdu in Wenchuan County. The areas hardest hit were within 100 kilometers (62 miles) of the epicenter. Dams, bridges, and schools collapsed, and about 3.5 million homes were destroyed. In some of the smaller cities and villages, as many as 80 percent of the structures were demolished. Estimates are that more than 14 million survivors have had to rebuild their homes.

Chengdu became a hub for rescue operations and humanitarian aid. The city’s hospitals and shelters were forced to erect tents to help care for the injured and homeless. The city itself, however, was mostly untouched. There was no disruption of essential services or business or business. Within a few days of the quake, Chengdu was back to its bustling normalcy.

It is easy to dodge a spear that comes in front of you but hard to avoid an arrow shot from behind.

明枪易躲，暗箭难防

Míng qiāng yì duǒ, àn jiàn nán fāng
CHIANG Ching-kuo

Jiǎng Jingguó 蒋经国

1910–1988  Former president of Taiwan

Chiang Ching-kuo, son of Chiang Kai-shek (also a former president of the Republic of China, i.e., Taiwan, 1949– ), was arguably the most influential political leader in Taiwan until his death in 1988. In a public opinion poll reported by Shijie Ribao (World Journal) in 2007, 65 percent of Taiwanese citizens surveyed ranked Chiang as the president who made the greatest contribution to Taiwan.

Chiang Ching-kuo was born in Fenghua, Zhejiang Province, in 1910. As a young man in 1926 he was sent by his father to the Soviet Union where he at first studied at Sun Yat-sen University for foreigners in Moscow as well as at USSR Military & Political Institute. After relations between Soviet leader Joseph Stalin and Chiang Kai-shek soured, the younger Chiang was sent to labor camps on the Soviet Union’s frontiers. He was allowed to return to China, with his Russian bride, in 1937.

During the Second Sino-Japanese War (1937–1945, known in China as the War of Resistance against Japan), Chiang held a number of key administrative positions, including institutional administrative commander of southern Jiangsu Province from 1939 to 1945 and foreign affairs administrator for the northeast administration of the Republic of China during the Chinese Civil War (1945–1949). In 1948 he was sent by his father, who had become president of the Republic of China, to “clean up” political and economic corruption in Shanghai, which was rife with powerful mafia-like gangs.

When Chiang Kai-shek went into exile in Taiwan in 1949, Chiang Ching-kuo was at his father’s side and became a powerful force in Taiwanese politics.

Chiang Ching-kuo was chairman of Taiwan’s Guomindang (Kuomindang, Chinese Nationalist Party) provincial headquarters from 1949 to 1950 and director-general of the political department of Taiwan’s military from 1950 to 1954. He then rose in rank in the government over the years, becoming first vice premier (1969–1972), then premier (1972–1978), and finally president (1979–1988).

Priorities as President

Chiang made developing a modern economic infrastructure a priority, emphasizing power, transportation, communications, and irrigation systems. He also expanded the influx of foreign investments. In 1965 direct foreign investments amounted to only $10 million. By 1979 direct foreign investments showed a net balance of $121 million. Other inflows of long-term private capital amounted to more than $300 million in 1979.

In foreign relations Chiang tried to reverse the decline of his government’s international standing after the United States switched course and sought better relations with mainland China. When Richard Nixon announced in 1971 his intention to visit the People’s Republic of China, where he signed the Shanghai Communiqué on 27 February 1972, the negative impact on Taiwan was
immediate. Taiwan was expelled from the U.N. in 1971 after the announcement of Nixon's proposed trip, Japan switched its recognition from Taiwan to China in 1972, and twenty-five other nations followed suit between 1971 and 1972.

Then when U.S. president Jimmy Carter formally normalized relations with China and invited Deng Xiaoping, general secretary of the Chinese Communist Party, to visit on 1 January 1979, Chiang, who was now Premier, launched his most intensive public relations outreach in the United States ever and strengthened his pro-Taiwan lobby in the U.S. Congress. His campaign succeeded on 10 April 1979, when Congress passed the Taiwan Relations Act, which provided the legal basis for the defense of Taiwan by the United States for years to come, thus promising U.S. military intervention should mainland China try to “retake” Taiwan by force.

**Political Policy**

Chiang also liberalized Taiwan’s domestic political system, which helped lead to Taiwan’s eventual democratization. His initial domestic political policy was the same as his father’s, that is, authoritarianism under one-party (Kuomintang) rule. However, he eventually instituted U.S.-style “affirmative action” programs to bring Taiwanese-born administrators into the ruling Kuomintang and all levels of government.

In 1986 Chiang Ching-kuo repealed the “Emergency Provisions” law, that is the martial law that limited civil liberties that had been in effect since his father Chiang Kai-shek had become President of Taiwan in 1950. Thus, for the first time on the island it became legal to organize opposition parties whose candidates could run for elected office.

Chiang Ching-kuo, like his father, absolutely opposed any demand for Taiwan’s independence. But unlike his father, Chiang Ching-kuo took significant steps to relax tensions with the mainland government. In 1987 he permitted Taiwan residents for the first time since the 1950s to conduct indirect trade and to make personal visits to the mainland; he permitted scientists, professional experts, and athletes from Taiwan to participate in international competitions with their counterparts from the mainland. Then, on 26 July 1987, Chiang allowed Taiwan residents to travel to Hong Kong to meet their Chinese relatives from the mainland openly (although “direct” contact on mainland soil was still officially forbidden). Finally, on 15 October 1987, under his orders the Kuomintang’s Central Standing Committee lifted the thirty-seven-year ban barring Taiwan’s residents from visiting their relatives on the mainland.

Chiang’s new policy had a profound effect on the Chinese people on both sides of the Taiwan Strait. The first week after the travel ban was lifted, some twenty thousand people in Taipei filed applications for permission to visit the mainland. As for indirect trade, Taiwanese businesses invested more than $50 million in fifty enterprises in Fujian Province alone during the first three months of 1988. China in 2008 was Taiwan’s largest trading partner; exports to China have accounted for one-third of Taiwan’s total exports since 2004; and more than 2 million Taiwanese maintain permanent residences in China.

Although Chiang’s reforms were substantial, historians believe Chiang was making plans for the reunification of Taiwan and the mainland just before his death. Chiang’s confidante and former student, Lee Huan, who was also the Kuomintang’s secretary-general, revealed after Chiang’s death that Chiang was prepared to begin negotiations with China’s Communist leaders to find a way to reunify the two governments and had sent envoys to “test the waters” for such negotiations in the years immediately preceding his death.

CHIANG Kai-shek

1887–1975  Military and political leader of the Chinese Nationalist Party and the Republic of China from 1928 until 1975

Chiang Kai-shek was the successor to Sun Yat-sen and political leader and military chief in China’s war against Japan; after his defeat by Mao Zedong in China’s Civil War (1945–1949) he escaped to Taiwan and established the Republic of China on Taiwan. As President of Taiwan, Chiang vowed to retake the mainland. With the help of the U.S. military and economic aid, Chiang did help to build Taiwan into a modern and prosperous nation.

Chiang Kai-shek is easily one of the three most important figures to shape modern Chinese history in the twentieth century, the other two figures being Sun Yat-sen and Mao Zedong. Sun led the revolution that overthrew the decaying Qing dynasty in 1911, Chiang became his successor as head of the Nationalist Party, and then fought a civil war against Mao’s Communist Party, which led to Mao’s victory on the mainland and Chiang’s establishment of the Republic of China on the island of Taiwan in 1950.

Chiang, also known as Chiang Chung-cheng in Chinese, was born in Fenghua, Zhejiang Province, on 30 October, 1887. He graduated from Paoting Military Academy in China in 1906 and then studied at the Tokyo Military Academy in Japan the next year. He joined Sun Yat-sen’s revolutionary party, called Tung Meng Hui, in 1908 and participated in the formation of the Nationalist Party (known in English as the Guomindang or Kuomindang). He then supported the Nationalists’ revolts against the Manchu-led Qing dynasty, which lead to the dynasty’s overthrow in December of 1911.

Because of Chiang’s extensive military training, Sun Yat-sen appointed Chiang as President of the Whampoa Military Academy in Canton in 1923. The Academy was non-partisan in its politics; famed Communist Party member Zhou Enlai was named its political director and famous Communist General Lin Biao got his start as a cadet there.

After Sun Yat-sen’s death from cancer in 1925, Chiang assumed the role of Sun’s successor. He was appointed as Commander-in-Chief of the newly formed Revolutionary Forces. Recruiting cadets from the Whampoa Military Academy, Chiang led them on the so-called Northern Expedition to attack various warlords in China in an effort to unite the country under the auspices of the Nationalist Party.

By 1926, Chiang’s forces had succeeded in reaching the outskirts of Shanghai, but unfortunately he was also out of money. Thus, Chiang made a pact with the devil, so-to-speak, that would ultimately come to haunt him as a leader for the rest of his life: He agreed to purge his forces of all Communist sympathizers and massacre Communist party members inside Shanghai in exchange for funding from Shanghai’s pro-Western industrialists and mafia-like gangs. The April 1927 Massacre, as it came to be known, was thus the first salvo in China’s ongoing Civil War between the Nationalists and the Communists. However, this pact allowed Chiang to enter the city without a fight and established the Nationalists as a pro-Western capitalist party. The disillusioned left wing of the party,
led by Sun Yat-sen’s widow, Soong Ching-ling, then set up a rival government in the city of Wuhan. The next year, Chiang married Ching-ling’s youngest sister, Soong Mei-ling, who had been educated by Western missionaries and studied at America’s Wellesley College. Chiang, who conveniently left his first wife for this auspicious union to the daughter of a family rife with money and Western ties, then converted publicly to Christianity himself.

To compete with the rival Wuhan government, Chiang made Nanking (Nanjing) the new capital of the Republic of China in 1928. He assumed various leadership positions in his government, including Chairman (Commander-in-Chief) of the National Military Council. He then personally negotiated with warlords across China, persuading them to join his government.

In one particularly bizarre episode, Chiang traveled to Xi’an in Shaanxi Province to meet with its military leader, the so-called “Young Marshal” Chang Hsueh-liang (Zhang Xueliang), on December 8, 1936. The Young Marshall took this opportunity to kidnap Chiang, refusing to release him unless Chiang agreed to stop his persecution of Chinese Communist Party members and instead to concentrate on fighting the Japanese military, which had already taken over Manchuria and established a puppet state known as Manchukuo there. Finally, Madame Chiang flew to Xi’an where she personally negotiated for her husband’s release with the aid of Communist leader Zhou Enlai. Chiang then agreed to stop fighting the Communists and form a “United Front” with them to fight the Japanese invasion. Young Marshal Chang then released Chiang and agreed to return as Chiang’s prisoner to Nanjing as a sign of his sincerity.

On July 7, 1937, full-scale war erupted between China and after Japanese troops attacked Chinese troops stationed near the Marco Polo Bridge outside Beijing. The better-equipped Japanese military quickly defeated the Chinese and gained control over the entirety of northern China. The Japanese Army then advanced southward. Chiang lost Shanghai in November and was forced to flee his capital of Nanjing, in December, which led to the massacre of civilians by Japanese troops in the infamous “Rape of Nanking.”

Chiang retreated to the interior of China and established a new capital in Chungking (Chongqing). His wife’s Western ties allowed him to gain American support, war material, and advisors after the Japanese bombing of Pearl Harbor forced America to enter World War II. The Communists, after initially suffering defeats from Nationalist troops, began to take advantage of the Japanese advancement to expand their territories by initiating guerrilla warfare against the Japanese (and the Nationalists) in the countryside.

In politics, Chiang always made loyalty his most important criterion for support, rather than ability or devotion to any particular political program. Furthermore, Chiang allowed rival cliques to divide the Nationalist Party so that he could play these factions against each other to his own advantage. Personal rivalry and factionalism thus paralyzed the Nationalists in their struggle against both the Japanese and the Communists.
In his government in Chungking, Chiang assumed the most powerful positions. He was named Generalissimo of the Nationalist Party from 1938 to 1946. After the Americans defeated the Japanese military, Chiang was finally named President of the National Government of the Republic of China, as a result of elections held by a newly formed National Assembly, which also adopted a Constitution. However, in China, he was always referred to by one title, wei yuan zhang (委員長), which can be translated as the Chairman or the Generalissimo.

In terms of policies, Chiang Kai-shek made little effort to present to the Chinese people attractive political, social and economic policies. His officials were corrupt and amassed huge personal fortunes while the nation’s ordinary citizens suffered. He demanded political and ideological unification of all of China under Confucian virtues, as he interpreted them, despite his conversion to Christianity. He blamed all China’s ills on the imperialist policies of Western powers and refused to accept any personal criticism. As a result he lost his earlier support of the United States for his government.

After he lost the Civil War against the Communists in 1949, he went into exile in Taiwan, which he declared to be the Republic of China. He was an authoritarian leader and imposed Martial Law, which had first been established on the mainland as “Emergency Provisions” during the Civil War and which limited many civil liberties, including free speech and the right to form opposition political parties. He continued to fight Communism relentlessly, vowing to take back the mainland from Mao. Chiang forbade any contact with the mainland by his citizens on Taiwan, including reading mainland newspapers, listening to mainland radio broadcasts or even receiving mail from relatives on the mainland.

Schools were not permitted to study subjects related to mainland China, including modern Chinese history. At the same time, Taiwanese were not allowed to talk about independence either.

After the Korean War broke out, the U.S. decided to support Chiang’s government as a bulwark against Communism’s spread in Asia and pledged military support as well as billions of dollars to build up Taiwan’s economy. The U.S. recognized the Republic of China on Taiwan as the sole legitimate government representing all of China until 1979, when President Carter normalized relations with the People’s Republic of China. By then, Chiang had already been dead for four years, never seeing his dream of “taking back the mainland” realized.

From its beginnings in 1981, China Daily has developed into the national English-language newspaper of China. With a circulation of 300,000 and an online edition, its target audience is tourists, business leaders, diplomats, and other visitors to China; it also has a large Chinese readership.

Founded in 1981, China Daily, China’s national English-language newspaper, began as a small but ambitious experiment, led by a corps of experienced journalists of cosmopolitan outlook, with a score of reporters recruited largely from among English language teachers and recent college graduates. Originally operating out of shabby borrowed quarters on the east side of Beijing, in two decades China Daily has grown into a large enterprise with its own modern compound and presses, hundreds of employees, a stable of ancillary publications and activities, and status as a quasi-official paper of record.

In 1993, the paper launched 21st Century, a weekly educational publication for students of English that subsequently branched into several editions for elementary, middle school, high school, and college levels as well as teachers. Other offshoots include Business Weekly, begun in 1985, and Beijing Weekend, begun in 1991, which both became regular inserts in the paper; the regionally-circulated weekly Shanghai Star, started in 1992; and color tabloids published in conjunction with Beijing’s hosting of the 1990 Asian Games, the 1995 Fourth World Conference on Women, and the 2008 Summer Olympics. Among other activities, the paper has hosted CEO roundtables for executives of multinational corporations, organized English language and journalism training courses, and sponsored an annual English speaking contest for college students beginning in 1996.

China Daily’s initial leadership was an eclectic mix. Publisher Jiang Muyue, who did not speak English but had long been associated with foreign-language publications, played a supportive but largely ceremonial role. The initial editor in chief was veteran journalist and author Liu Zhunqi, who had joined the Communist underground as a student at the missionary-run Yanjing University in Beijing and later worked for the U.S. wartime information center in Chongqing. Although he was in poor health due to mistreatment during the Cultural Revolution, Liu contributed a quiet gravity and distinction.

The undisputed mastermind and energizer of the early China Daily was Feng Xiliang, a longtime editor of
the weekly *Beijing Review*, who had studied journalism at St. John’s University, a missionary school in Shanghai, and earned a master’s degree in journalism from the University of Missouri. As head of the paper’s founding commission and then managing editor (1981–1984) and editor-in-chief (1984–1987), Feng often stated that *China Daily*’s objective was to help foreigners understand China and China understand the world. Indeed, a large (although usually unacknowledged) proportion of *China Daily*’s readership is composed of Chinese readers.

Among Feng’s innovations were the use of foreign news agency reports in addition to the official Xinhua News Agency for international news, an emphasis on striking layout and large headlines, and prominent use of photographs. Rather than relying on translations from Chinese to English, Feng emphasized writing of news and features as well as commentaries directly in English. As part of his effort to reach international audiences through colloquial language that broke with political jargon, he recruited advisors and “polishers” from Britain, Australia, and the United States; encouraged study abroad for young Chinese reporters; and initiated exchange agreements and training programs for staff.

Feng, who later was an advisor to the *South China Morning Post* in Hong Kong, developed Alzheimer’s disease and died in Beijing in 2006 at age eighty-six. Succeeding him as chief editor were Chen Li (1987–1993), (who also passed away in 2006), Zhu Yinghuang (1993–2004), and Zhu Ling (b. 2004), all men—although the initial senior editorial leadership included a number of older women, and a female reporter from the original staff, Huang Qing, rose to the level of first deputy chief editor.

Along with other major newspapers in Beijing, *China Daily* provided overwhelmingly sympathetic coverage of the student protests in Tiananmen Square during the spring of 1989, with many of its journalists joining in at the height of mass demonstrations. Like other news organizations, the paper experienced a retrenchment period after the declaration of martial law and military crackdown of 4 June, including a temporary reduction in size from eight to four pages and adoption of the official description of the demonstrations as a “counterrevolutionary rebellion.”

Often described by foreign media as “official,” and technically under the supervision of the Propaganda Bureau of the Central Committee of the Chinese Communist Party, *China Daily* nevertheless resists definition as a simple mouthpiece. Along with carrying pronouncements that are clearly obligatory, the paper has developed a reputation for lively, original reporting, with a staff that prides itself on professionalism. Its upstart traditions, extensive international ties, roster of foreign employees and goal of reaching foreign tourists, business people, diplomats, and other expatriates and visitors gives it a distinctive, if quixotic, status.

For millennia China has influenced and been influenced by the world—scientifically, agriculturally, politically, culturally, and economically—and in 2008 had a population of 1.33 billion, larger than any country’s. Despite past political turmoil and natural and human-made disasters, China’s current government has reasserted an imperial unity and expanded its global influence beyond all earlier limits.

China is a very big country. Today China’s land and water mass is nearly 9.6 million square kilometers (fourth after Russia, Canada, and the United States). Its land boundaries extend to fourteen countries—a world record it shares with Russia, although China’s borders out-measure Russia’s by about 2,000 kilometers. The 1.33 billion people living within those borders (as of 2008) give China the distinction of being by far the most populous land on Earth. China is also a very old country. Homo erectus populations lived there about 900,000 years ago, and modern Homo sapiens arrived about 40,000 years ago. Agriculture dates from about 10,000 years ago; Chinese state-building and civilization arose, initially in the Huang (Yellow) River valley, after about 4,300 years ago, and attained lasting and distinctive forms with the establishment of the Shang dynasty (1766–1045 BCE).

China’s role in world history is correspondingly prominent. To begin with, its distinctive civilization affected neighboring peoples in east Asia—Koreans and Japanese to the east, steppe nomads to the north and west, and tropical gardeners to the south. China has always retained primacy in that part of the world thanks to the skills, the numbers, and the economic and political prowess of its population. As transport and communication improved over time, China’s influence reached ever more widely across Asia, and Chinese civilization continually enriched itself by importing new skills, new knowledge, and new things from afar. Beginning about 100 BCE, with the opening of organized caravan trade along the so-called Silk Roads, this process of interaction began to affect western Asia and even distant Europe as it established an Old World web that eventually expanded around the globe after 1500, creating the tumultuous world we know today.

Early China to 221 BCE

Chinese writers preserved a uniquely comprehensive political narrative. It begins with mythical divine rulers, and no archaeological trace of the first merely human dynasty, the Xia (c. 2100–1766 BCE), has yet been discovered. But in the 1920s excavation at Anyang, seat of the last rulers of the Shang dynasty (1766–1045 BCE), uncovered thousands of oracle bones inscribed in a script close enough to modern Chinese writing to be readily interpreted. They and other remains show that basic elements of subsequent Chinese civilization had already appeared by 1300 BCE.

Anyang is situated where the Huang (Yellow) River of northern China traverses a region of soft, windblown
loess soils. That was where early farmers had begun to raise millet, which was later supplemented by wheat and barley coming across Asia from Mesopotamia. The Shang armies also used horses, chariots, and compound bows, introduced from the western steppe. But script, religion, and family patterns were unique and closely resembled later Chinese practices.

Far-reaching changes came under the Zhou dynasty (1045–256 BCE). First of all, rain-watered agriculture, which had been basic for the Shang peoples, came to be supplemented and soon overshadowed by extending cultivation to the fertile soils of the river floodplain, a process that required massive building of dikes and canals to control and direct the flow of water. When successful, this water engineering assured ample moisture for the harvest and diminished north China’s dependence on uncertain monsoon rains. It also vastly expanded the area of cultivation as the labor of generations of conscripted farmers

The oldest printed map in any culture, a map of West China (Di Li chin Tou) in the Liu Qing Tou (Illustrations of Objects mentioned in the Six Classics), an encyclopedia circa 1155 BCE. Province names are written in white on black, and the line of the Great Wall is clearly visible along the top half of the map.
extended dikes and canals up and down the river valleys and across the coastal plain of north China.

Drainage canals permitted early Chinese farmers to irrigate their new fields and thus to raise rice. Rice grew naturally in shallow water along lake shores and river banks of Southeast Asia, where local gardeners began to harvest it as early as 8000 BCE. But artificial dikes and canals, like those the Chinese built in the northern Huang River valley, enormously extended the area of suitably shallow water. Consequently, by 200 BCE rice had become the main food of China’s rapidly growing population, as it remains to this day.

When low-lying river floodplains began to fill up with cultivated fields, Chinese farmers took on the even more strenuous task of leveling slopes, building dikes around small, artificially leveled fields called “paddies,” and channeling even very small streams to bring water to them. This improvement allowed hillsides in what eventually became central and southern China to produce rice almost as abundantly as the naturally flat river floodplains did.

As this enormous engineering effort gradually expanded across the landscape—a process that took millennia and may not have reached its final limits in the Himalayan foothills even today—China’s population began to assume the close-packed density and imposing numbers that still characterize the country. Human muscles, assisted by shovels and wheelbarrows (a Chinese invention), did almost all the work. It remains the most extensive, drastic, and successful remodeling of a natural landscape ever undertaken by humankind.

**Impact of Rice Cultivation**

In time similar rice paddies spread to Korea, Japan, the Philippines, Java, Sumatra, and all the great river valleys of Southeast Asia, as far away as the Ganges River in India. Wherever wet rice cultivation spread, dense rural populations arose and supported royal or imperial governments. Something like half of humankind came to depend on this sort of agriculture and still does. And because its two great rivers drained such extensive watersheds, China remained by far the largest and most populous country among all the rice-growing lands.

Rice, like other grains, must be harvested when ripe, and harvests must be stored to feed the farmers throughout the year and provide seed for next year’s harvest. Stores of grain in turn allowed governments and an ever-growing class of landowners to arise by collecting part of the harvest as taxes and rents, thus turning once-independent farmers into peasants. Rice-growing peasants had more to spare than other grain farmers, since a single rice seed ordinarily produced several stalks carrying more than a hundred seeds in all, while wheat farmers of medieval Europe made do with a seed-to-harvest ratio of only about 6 to 1. But this did not mean that Chinese farmers were rich. Instead, taxes and rents rose high enough to transfer extra food to city folk—rulers, landlords, artisans, and casual laborers. Accordingly, from the time rice became the staple crop in China, cities grew larger than was possible in rain-watered lands elsewhere.

Despite its unrivaled productivity, irrigated rice cultivation had serious costs. Standing water in paddy fields...
made malaria and the debilitating disease schistosomiasis very common; for a long time the Yangzi (Chang) River valley—today the most fertile and populous region of China—remained notoriously unhealthy and was less densely populated than the north.

In the north, however, China’s other main river, the Huang, reacted to confinement between human-made dikes by clogging its channel with silt it had picked up when flowing through the soft loess soils. As happens along the lower Mississippi River today, silt soon raised the lower course of the Huang above the level of the land outside the dikes. Efforts to forestall floods by building higher dikes could stave off disaster for a while, but sooner or later the river broke through, and resulting floods became greater and more damaging than before. The Huang River thus earned the nickname “China’s sorrow.” No other river carries so much silt, and the Huang is correspondingly unstable. In historic times unusually high floods on several occasions have shifted its lower channel by several hundreds of miles.

Increasing Rule of Landowners

The large-scale water engineering that reshaped China was initiated by enterprising local landowners who conscripted farmers to do the work. As new fields came into existence, landowners’ income and authority increased, and local rulers emerged who were strong enough to pay no attention to the distant emperors. But from the start they quarreled among themselves. Centuries of upheaval ensued, while rising agricultural wealth sustained intellectual and cultural efforts to contain the ills of intensified warfare among all the rival states.

Confucian and other schools of thought competed in words as vigorously as the rival armies did in battle, defining much of what became classical rules of behavior for later generations. But ideas in and of themselves had little to do with the ultimate restoration of public order. Rather, when the Zhou dynasty died out in 256 BCE, even the pretense of imperial unity was abandoned; the Warring States period (475–221 BCE) came to a climax in 221 BCE when a single warlord from the state of Qin on the northwest borderland subdued all rivals. His rule (Qin dynasty, 221–206 BCE) did not long survive. Instead, after another bout of warfare, China attained a more lasting imperial and cultural unity under the Han dynasty (206 BCE–220 CE).

Imperial China (206 BCE to 1912)

The Han dynasty turned out to be a lasting model for later dynasties in Chinese history, and the advantages of imperial government in uniting the fertile river valleys of north and south China with shifting control over borderlands were so great that whenever a dynasty collapsed, a new emperor and dynasty soon emerged after relatively brief civil wars. Today, for all its ideological departures, Communist China looks like a new dynasty of a quite traditional sort. This amazing continuity presumably reflects the fact that Chinese people came to prefer unity and learned to feel themselves a single people in spite of local dialectical differences that made their spoken language unintelligible across long distances.

Written characters, however, can also be voiced in different ways and used to record languages as different from Chinese as Japanese and Korean, just as the numerals 1, 2, and 3 represent entirely different words in English, French, and German. Eventually the characters of classical Chinese literature, as edited, elaborated, and preserved by Confucian scholars—and then propagated by formal education among untold millions of Chinese across two thousand years—provided a set of ideas and precepts that both restrained and guided rulers and also taught obedience to the emperor and his officials, just as long as the Mandate of Heaven kept him on the throne. The Han dynasty was the first to patronize Confucian scholars, and the emperors spent much time performing ancestral rituals designed to maintain good relations with heaven and the lesser spirits, as Confucius (551–479 BCE) had prescribed. Even when Buddhism won a large following at court and in the country at large, subsequent dynasties continued these rituals to be safe from supernatural harm.

The Confucian style of commitment to imperial unity was in turn sustained by the way bulky goods, which were paid as taxes in kind, could be carried in barges along canals (initially constructed for drainage and irrigation), and delivered to the imperial capital across long
distances. At first the Yangzi Valley remained isolated from the Huang River network of canals, and thus its resources could not easily reach the imperial court. But in 611 CE the Grand Canal was opened, connecting China’s two principal river systems so that canal boats could move safely and cheaply to and fro between the imperial capital, which remained in the north, and the far reaches of the Yangzi Valley. Nothing close to such a capacious, cheap, and safe transport system existed elsewhere. The Chinese government and people prospered as a result, spreading rice paddies and building cities throughout the hills and valleys of the Yangzi River watershed, more

During the Han dynasty, China established peaceful relations with nomad chieftains, giving them goods they desired as gifts in return for obedience to the Chinese emperor. But such treaties often broke down and raids began anew. This particular illustration is an early Qing dynasty representation of the exchange of tribute.
than doubling China’s size and resources by the time the lengthy pioneering effort neared completion.

Massive expansion southward in turn allowed the government to cope, not quite so successfully, with the problem of protecting itself and its subjects against outside dangers. Enlarged tax income made it easy to elaborate court rituals for propitiating heaven and other powerful spirits. Keeping steppe nomads at a distance and preventing their destructive raids were more difficult. Horses raised themselves on the grassy steppes; nomad tribesmen spent much of their lives in the saddle, guarding their herds against outsiders, and, when opportunity offered, raiding horses from one another or invading Chinese borderlands to seize grain or anything else they found useful.

**THE GREAT WALL—AND ITS IMPACT**

Men mounted on horses moved far faster than infantry could ever hope to do. Because fortified walls were an obstacle horsemen could not easily overcome, the famous Great Wall of China was constructed across centuries in hope of stopping their raids. Infantry equipped with crossbows (a Chinese invention) could indeed repel steppe attackers from on top of the wall as long as enough bowmen were already in place to meet them. But hundreds of miles of wall and open country between its gaps required more men on guard than even the Chinese empire and its canal transport system could support day after day, year round.

Two alternatives existed: hiring nomads to stop their fellows from attacking by paying them with what they might otherwise have seized or training and supplying enough Chinese cavalymen to meet and defeat steppe raiders. Both methods were tried over and over, but the problem would not be lastingly solved until after 1750. Hired nomads could change sides at any moment, while keeping horses in China was horribly expensive. In the absence of natural grass, a horse ate many times as much grain as a man needed, so matching steppe horsemen with enough Chinese cavalymen was costly. A more successful tactic was to establish peaceful relations with nomad chieftains, giving them goods they desired as gifts in return for ritual recognition of obedience to the Chinese emperor. But such treaties often broke down, and raids began anew.

Nonetheless, over centuries the effect of raiding and gifting between China and the peoples of the steppe was to familiarize nomads with more and more aspects of Chinese civilization, eventually spreading key Chinese inventions far and wide throughout Eurasia. Chinese armies and armed expeditions also extended Chinese influence westward from time to time, beginning in 101 BCE, when the Han Emperor Wudi sent an expedition to the Ferghana Valley in modern Uzbekistan to bring back a breed of “blood-sweating” horses capable of carrying heavily armored men on their backs. For centuries thereafter caravans connected China with western Asia along what westerners called the Silk Roads. As a result, communication within the Eurasian web attained a new velocity and regularity that increased little by little and reached a climax under the Mongol conqueror Chinggis Khan (often spelled Genghis Khan, 1126–1227) and his successors.

Nonetheless, over centuries the effect of raiding and gifting between China and the peoples of the steppe was to familiarize nomads with more and more aspects of Chinese civilization, eventually spreading key Chinese inventions far and wide throughout Eurasia. Chinese armies and armed expeditions also extended Chinese influence westward from time to time, beginning in 101 BCE, when the Han Emperor Wudi sent an expedition to the Ferghana Valley in modern Uzbekistan to bring back a breed of “blood-sweating” horses capable of carrying heavily armored men on their backs. For centuries thereafter caravans connected China with western Asia along what westerners called the Silk Roads. As a result, communication within the Eurasian web attained a new velocity and regularity that increased little by little and reached a climax under the Mongol conqueror Chinggis Khan (often spelled Genghis Khan, 1126–1227) and his successors.
To begin with, China had much to learn from Indians and west Asians. Buddhist holy men began to filter into China even before the Han dynasty collapsed; during the years of civil strife and divided sovereignties that ensued, the new religion won many adherents, including the emperor who founded the Sui dynasty (581–618 ce) and reunited China in 589. Buddhists retained imperial favor until 843, when Confucians succeeded in disbanding Buddhist monasteries and prohibiting their religion. But the Confucians had to borrow much from the Buddhists in order to refute them, so restored Confucianism came to resemble the other high religions of Eurasia more closely than before. Buddhist sects continued to exist, especially among the poor and oppressed, and often sparked rebellions when a dynasty began to weaken.

Buddhist art also affected older Chinese styles profoundly. In particular, the landscapes and portraiture of classical Chinese painting owed much to their Buddhist predecessors. More important for Chinese society as a whole was the fact that Buddhist monasteries introduced the Chinese to the habit of buying and selling goods for daily consumption. In ancient China money had played almost no role. Taxes, rents, and services were paid in kind, and peasants lived on what was left after taxes and rents had taken their share. Buddhist monks, however, coming from India along the Silk Roads, were accustomed to selling the produce of landed estates that pious believers deeded to them and then using money to buy whatever the monastery needed. Before their dissolution in 843, each monastery in China therefore became the center of a local market; Chinese townsmen and peasants far and wide soon learned the uses of money by buying from and selling to the monasteries.

**Cash and Carry**

Use of money became widespread enough that under the Song dynasty (960–1279), the imperial government found it convenient to collect taxes in money rather than in kind. Before a century had passed more than half the government’s income took the form of first metal, then paper currency. Consequently, millions of ordinary peasants started to sell part or all of their harvest to pay taxes. Thereupon, goods of common consumption—rice, salt, iron, silk, and innumerable others—began to circulate along the waterways of China. Even a small difference of price made it worthwhile for merchants to carry goods to distant markets along the canal system; all the advantages of specialized production, which the Scottish economist Adam Smith later analyzed so convincingly, came into operation among something like 100 million Chinese. China began to grow in population, wealth, and skill more rapidly than ever before, while the government fanned the whole process by spending its cash income on whatever it needed.

Simultaneously, agriculture intensified after a new species of early-ripening rice reached China from the south after 1000. Wherever water was available all summer long, this meant that Chinese farmers could raise two crops a year, thereby doubling production per acre. Needless to say, the effect was enormous. Work intensified, and

**Paper money was invented in China, and quickly spread around the globe. This particular note is from 1380.**
population increased and became denser than ever, since throughout the well-watered plains families could survive on half as much land as before. The social discipline of working ceaselessly to keep fields, dikes, and canals in order made the Chinese workforce far more diligent and productive than most others, and eventually gave it an enormous advantage in competition with foreigners, as we shall see.

This superiority began to show under the Song dynasty, when important new industries appeared, not the least of which was the manufacture of guns and gunpowder. Newly perfected porcelain began to rival silk among China’s exports, and, when the discovery of how to make coke out of coal solved a long-standing fuel shortage in northern China, large-scale iron works multiplied. Fragmentary tax records show that iron production almost quadrupled from 32,500 tons a year in 998 to 125,000 tons in 1078, but that pace was not long sustained, and by 1260 production had dropped to a mere 8,000 tons per year.

**GUNS AND GUNPOWDER**

Chinese officials shaped by the Confucian tradition distrusted captains of industry almost as much as soldiers. Such persons, left to themselves, officials feared, might become rich and powerful enough to threaten their public authority. So the fact that officials closely supervised weapons manufacture from the start, and then monopolized the sale of iron agricultural implements in 1083, may have upset prices and made iron production unprofitable. But no one knows what actually happened. We do know that most imperial tax income went to supporting armies along the steppe frontier, and as its steppe neighbors became more formidable, the Song government began systematically to reward the inventors of new and more efficient weapons. Gunpowder weapons accordingly came quickly to the fore.

The Song government soon needed all the help it could get, for in 1127 it was driven from northern China by a new tribal steppe confederation. Nonetheless, strenuous investment in naval vessels, defended by newfangled guns and catapults as well as by crossbows, allowed the dynasty to survive as the Southern Song (1127–1279), ruling from a new capital in the south on the Yangzi River. But after a new steppe confederacy under Chinggis Khan conquered north China in 1227, his grandson Khubilai Khan ordered Chinese artisans to build a navy for him, and he used it to overrun south China, thus founding the Yuan dynasty (1279–1368).

**MONGOL EMPIRE**

The massive commercialization of Song China and accompanying improvements in weaponry soon spread far and wide within Eurasia. Steppe peoples were the first to feel the impact, as the rapid development of their military formidable demonstrated. Indeed, the Mongol Empire at its height extended across all of Asia to the shores of the Mediterranean and northward into Russia. No empire since has equaled its extent. For two or three generations after the 1240s, thousands of soldiers, merchants, captives, and caravan attendants moved continually back and forth across the steppe.

The mingling of peoples that the Mongol conquests provoked was extraordinary. We know that when a papal emissary, William of Rubruck, reached the Mongol capital at Karakorum in 1253 he met the wife of a goldsmith who had been born in Flanders a few miles from his own birthplace; about a century later the Muslim traveler Ibn Battuta tells how he met a merchant from his native Morocco in south China. Innumerable such encounters spread detailed knowledge far and wide about superior Chinese skills. It is striking to realize that the

---

The Chinese invented gunpowder and rocketry, which was then exported to the rest of the world. Efficient handguns were developed after about 1550.
three inventions the English philosopher Francis Bacon would later declare to have made Europe modern—the compass, gunpowder, and printing (together with its essential partner, paper-making)—all reached Europe from China by word of mouth and without leaving any written record. Motifs of Chinese painting also traveled throughout the Muslim world, eventually so misunderstood that stylized drawings of the massive Yangzi River gorges became perches for peacocks.

Borrowing from afar always involved transformation and adjustment to a new environment. That had been true of Chinese borrowing from India and west Asia in earlier times as they developed their own Buddhist sects and forms of mounted warfare. European, Indian, and west Asian responses to gunpowder, printing, and the compass were just as varied, but everywhere the new Chinese techniques affected warfare, shipping, and communication, even though Muslims at first rejected printing.

Native Chinese were never fully reconciled to foreign rule, and when the Huang River broke through its dikes and, before finding a new path to the sea, devastated much of northern China, they knew that the Mandate of Heaven had been withdrawn from their Mongol rulers. Plague also ravaged China in the 1330s, and the government mismanaged the paper currency by indulging in reckless inflation. Not surprisingly, public order broke down until, after years of fighting, a new and authentically Chinese dynasty, the Ming (1368–1644), united the country once more. As the Mongol power collapsed, caravan linkages across Asia diminished without breaking off entirely. But the Chinese promptly began to explore alternative sea routes after defenses along the northwest frontier seemed sufficiently secure, allowing the third Ming
emperor, Zhudi (1402–1424), to embark on an ambitious program of overseas exploration and expansion into the Indian Ocean.

Altogether, six armadas, dispatched between 1405 and 1433, carried hundreds of ships and thousands of men to the shores of the Indian Ocean, touching on the coast of east Africa and even penetrating the Red Sea. Wherever the ships appeared the Chinese admiral, Zheng He, collected rarities as gifts and demanded that local rulers recognize the dominion of the Chinese emperor. The scale of these expeditions dwarfed that of the Portuguese explorer Vasco da Gama, who started on his voyage to India in 1497 with just four ships; but unlike the Portuguese discovery of the sea route to India, Zheng He’s voyages had no enduring effect. Instead, when the next Ming emperor incautiously led an army onto the steppes in 1449, his Mongol enemies captured him. Even though he was released the next year, memories of Chinggis Khan were far too fresh for the Chinese to spend any further resources on the fleet. Instead, sailing the seas was forbidden until the 1570s, and the imperial navy was allowed to rot away.

**OVERSEAS TRADE DECLINES**

Private overseas trade from Chinese ports dwindled as long as sailing remained illegal, but Chinese emigrants had already begun to prosper throughout southeast Asia and continued to thrive until recent times. So the Chinese never withdrew entirely from the seas. What might have been if they had anticipated Europeans by crossing the Earth’s oceans and reaching both the Americas and Europe sometime before 1450, as they were certainly capable of doing, beggars the imagination. This is perhaps the most dramatic turning point in world history—an abdication whose long-term consequences still reverberate.

---

*Photo by Joan Lebold Cohen.*
Nevertheless, from their own point of view, China's rulers were wise in concentrating public effort on safeguarding their landward frontier while closely regulating trade with the European and other foreign merchants who began to visit their ports after 1520, when the first Portuguese ship showed up. For little by little the Chinese began to prevail against the steppe horsemen, and by 1750 Chinese frontiers had shifted far to the west, approximately doubling the total area of the empire and subjecting millions of Tibetans, Turks, Mongols, and Manchus to Chinese rule.

Circumstances go far to explain this seismic shift in China's relation with the steppe peoples. First of all, beginning in the time of the Mongol empire, bubonic plague spread across Eurasia, killing up to one-third of the population on its initial onslaught. Probably the plague bacillus had emerged from one of its long-standing homes in the Himalayan foothills when Mongol horsemen raided northern Burma (Myanmar) in 1252–1253 and then carried it back in their homeland, where a new array of burrowing rodents—the normal carriers of the infection—offered the bacillus a new set of hosts.

Within a few decades the disease became endemic across the entire Eurasian steppe, infecting burrowing rodents of several species; after the initial catastrophic attacks on human populations in China, west Asia, and Europe between the 1330s and 1349, lesser outbreaks of plague recurred from time to time across the agricultural lands of Eurasia until as recently as the 1920s. We have no written record of what happened among steppe dwellers, but it seems certain that their exposure was greater than among farmers, since wherever they pitched their tents the reservoir of infection among the burrowing rodents of the grasslands lay immediately under their feet. Nomad populations shrank substantially as a result, and nomad strength in war diminished accordingly.

Eventually people adopted folkways that diminished exposure to the plague bacillus: For example, in 1920 Manchus knew not to come near infected marmots in their homeland, so it was the ignorant, immigrant Chinese who killed them for their fur and caught the plague. This development brought European and Japanese doctors to the scene, where they duly discovered *Pasteurella pestis* and its mode of transmission between rodent and human populations. The plague today has therefore ceased to matter among humans, even though the bacillus now infects burrowing rodents around the Earth, even in the United States.

The development of more efficient handguns and crossbows after about 1550 and of better supply systems was another factor in weakening nomads against the Chinese (and Russian) armies. The Ming dynasty began to expand its power into the steppe, organizing mobile armies of foot soldiers, equipped more often with crossbows than with hand guns, and supplied by wagon trains trained to form defensive circles in case of nomad attack. These tactics proved effective and soon allowed Chinese settlers to begin to move into the grasslands wherever moisture was sufficient to sustain crops.

**SECOND CONQUEST**

Nonetheless, between 1644 and 1683 China suffered a second conquest from the steppes when Manchu cavalrymen took advantage of quarrels among rival Chinese generals, seized Beijing, and proclaimed a new dynasty, the Qing (1644–1912). The Manchus were already familiar with Chinese ways and were correspondingly more acceptable to their Chinese subjects than the Mongols had been. Their cavalry, supplemented by Chinese infantry, made a formidable force and allowed the Chinese to expand their power westward until they encountered the equally expansive Russian Empire. Thereupon, two treaties—signed in 1689 and again in 1727—defined the new boundaries between China and Russia. The last steppe confederacy to resist the Chinese met defeat in 1755, and Tibet was subdued between 1755 and 1779, bringing China's imperial boundaries to limits that still prevail.

**EAST/WEST EXCHANGE**

This expansion westward was also sustained by a massive growth in China's population. Here it was crops introduced from the Americas—potatoes, sweet potatoes, and peanuts—that made the most difference. Sweet potatoes, in particular, tolerated poor soils and could grow on higher slopes and other marginal locations where rice could not thrive. They therefore became significant in south China, while ordinary potatoes played the same role on a somewhat smaller scale in the north.

Communication with Europe expanded and became far more precise after 1601 when a Jesuit mission was
admitted to the Ming court. Surprisingly, the Chinese made the Jesuits responsible for correcting the Chinese calendar to fit the seasons properly. The emperor and his ministers believed that rituals assuring the harvest could work only when offered at the right time of year, and nothing mattered more than that. Later they also asked the Jesuits to cast cannon for their armies and to supervise a ground survey and then make a map of the entire empire.

Jesuit missionaries continued to be active at the Chinese court until 1706 and year after year reported everything they did to Rome. They attracted only a handful of converts but nevertheless found much to admire in Chinese practices; European readers of their detailed reports often did so, too. In particular, the long-standing Chinese practice of recruiting government officials by written and oral examinations seemed rational to learned Europeans, and several German states imitated the Chinese example early in the eighteenth century. A little later Chinese decorative art, as transmitted by porcelain and embroideries, became suddenly fashionable as well. And radical eighteenth-century French writers, such as Voltaire, thought the Chinese example of a country without priests or revealed religion was far superior to European superstition. In short, the two civilizations were exchanging ideas among experts as never before and on a scale that began to affect them both in far-reaching ways.

Overall, therefore, the Chinese government and economy prospered at home and abroad until the closing decades of the eighteenth century. But by about 1775, population pressure on the land began to provoke rebellions, and trade in opium imported by the English East India Company created addicts in Guangzhou (Canton) and adjacent regions despite official efforts to prohibit it. The Chinese rebuffed a British effort to negotiate a trade treaty in 1793 when Lord Macartney refused to prostrate himself before the emperor, as court ritual required. Thereafter, frictions over opium continued to mount until the British navy showed up on the Chinese coast in 1841–1842 and proceeded to bombard coastal ports into submission and even interrupted traffic on the Grand Canal. A series of “unequal” treaties ended this Opium War, transferred Hong Kong to British control, opened Chinese ports to European traders, established a uniform 5 percent tariff, and gave Europeans the protection of consular and mixed courts for settling disputes among themselves and with the Chinese.

Dead Chinese soldiers at Fort Taku, Tianjin, in 1860. These soldiers were killed by Anglo-French forces in one of the key battles of the second Opium War. PHOTO BY FELICE BEATO.
Such harsh humiliation was impossible for the Chinese people to accept, while European admiration for things Chinese turned into something like disdain for their helplessness. At the bottom of Chinese society, half-baked efforts to adopt European secrets of power began to spread among angry young men, as the Taiping Rebellion (1850–1864) showed. It was led by a man who, after repeatedly failing the imperial examinations, met an American Baptist missionary from Tennessee and subsequently claimed to be the younger brother of Jesus Christ, sent by God to bring heaven to Earth and rid China of its corrupt foreign rulers in the bargain.

For a few years the Taipings met with widespread success, overthrowing the imperial administration in south China and almost capturing Beijing. But Britain and France sent armed forces to safeguard their treaty rights, and after occupying Beijing and sacking the emperor’s summer palace in 1860, they joined forces with local Chinese militias and defeated the Taiping rebels by 1864. By then between 20 and 30 million Chinese had died, and much of the country had been laid waste. The dynasty barely survived, harassed by increasing diplomatic and military pressure not just from Britain and France but also from Russia, a newly united Germany, and most acutely from neighboring Japan. In 1900 the so-called Boxer Rebellion, provoked this time by an underground Buddhist sect, tried to drive the foreigners away, only to meet defeat. Desperate efforts at self-strengthening ensued, but starting to build a European-style army merely created a disloyal officer corps that joined rebellious students to overthrow the dynasty in 1912.

**Post-Imperial China (1912–present)**

Although China evolved from a republic to a people's republic under Communist rule, and then to a nation reopened to the free world under the leadership of Deng Xioping in 1978–79, the rebellions, wars, and general disorder in the years after the Qing dynasty closely resembled previous dynastic transitions.

**THREE PROMINENT FIGURES**

Three figures dominated the tumultuous political scene in republican China after 1912: Sun Yat-sen (1866–1925); Chiang Kai-shek (1887–1975), and Mao Zedong (1893–1976). Sun Yat-sen was trained abroad as a medical doctor, but turned into a revolutionary conspirator before becoming the first president of Republican China (1912–1949) in 1912. As head of the newfangled Chinese Nationalist Party (Guomindang), he aimed to reshape Chinese society, but local warlords operating in many provinces
resisted his leadership, and by the end of his life the Guomindang found itself sharing power with the rival Communist Party, modeled in part on the Russian example.

Chiang Kai-shek, trained as a soldier in Japan and Russia, became head of a new military academy organized by the Guomindang before succeeding Sun Yat-sen after Sun's death. Chiang quarreled with the Communists in 1927 and compelled them to withdraw from around Guangzhou, where Mao Zedong had already begun to recruit an army of guerrillas among impoverished peasants. After months of marching the Communists found refuge in the northwest, where supplies of arms could reach them from across the Russian border.

Chiang then set out to defeat competing warlords and was able to occupy Beijing before the Japanese army invaded Manchuria in 1931 and then China proper in 1937. Chiang's armies eventually had to retreat up the Yangzi River all the way to Chungking (Chongqing), while Japan set up a puppet Manchu emperor over the rest of China. Nonetheless, the United States and Britain recognized Chiang's government throughout World War II and made Chiang's China a founding member of the United Nations Security Council.

Then Japan's defeat in 1945 reopened the struggle between Chinese Communists and the Guomindang (Nationalist Party), and despite U.S. efforts to support Chiang, Mao's forces prevailed, setting up the People's Republic of China in October 1949. Chiang and a remnant of his army withdrew to the island of Taiwan, where their successors still remain in power.

Chaos before and after the end of the Qing dynasty closely resembled previous dynastic takeovers, and Mao's government behaved very much like a new dynasty, even though it depended upon a small circle at the top of the Communist Party rather than upon a court circle of Confucian officials serving a new ruling family.
Internationally, Mao’s victory at first seemed to strengthen the Communist cause enormously, and for a while U.S. politicians were much agitated by their “loss” of China. Yet, in fact, Russian and Chinese Communists were rivals as much as allies from the start, and 1968–1969 border disputes even led to brief armed collision between the two governments. U.S. president Richard Nixon took advantage of this rift to reestablish diplomatic relations with China in 1972, thus recognizing its growing economic and political power.

Since then China has gone from strength to strength. Mao’s successors, notably Deng Xiaoping, relaxed efforts at collectivization of farm land in 1981, allowing peasants to produce what they chose and to sell their surpluses at will. Parallel private competition with state-run factories soon provoked urban and industrial expansion on a quite extraordinary scale—as much as 12 percent growth in gross national product a year. Chinese products soon became cheaper and often better than anything available elsewhere. Exports swelled accordingly, and other countries, with the United States in the lead, went deeply in debt by importing all sorts of consumer goods from China. In 2008 China hosted the Olympic Games, a crowning glory for a government that has never ceased to face foreign criticism for its suppression of human rights in Tibet and elsewhere.

And yet all is not well in the new China. Ecological pollution is widespread and acute. Population presses heavily on resources, and official efforts to diminish the birth rate by prohibiting couples from having more than one child may strain normal generational transitions. The vast and controversial Three Gorges Dam under construction on the Yangzi River, and scheduled for completion in 2009, has displaced more than a million people and may damage age-old methods of irrigation; and innumerable other disasters, like the 2008 earthquakes in Sichuan Province may arise. But so far, at least, the Communist government has been successful in reasserting political unity, restoring the nation’s wealth, and expanding China’s worldwide influence beyond all earlier limits and can triumphantly expect the future to take care of itself.

China Institute in America

Huá-ēi Xiéjínshè 华美协进会

China Institute in America is a nonprofit educational and cultural institution located in New York City. It operates programs in both the United States and China with the hope of fostering understanding between the two nations.

China Institute in America was founded in 1926 as a nonprofit educational and cultural institution to promote a deeper understanding of China through programs in education, culture, business, and art in the belief that cross-cultural understanding strengthens the global community. Its programs are designed for people of all ages and backgrounds, including children, businesspeople, artists, and educators.

China Institute was founded by a group of American and Chinese educators that included John Dewey, Hu Shih, Paul Monroe, and Kuo Ping-wen. The idea for the institute was born after the educational philosopher John Dewey spent eighteen months lecturing and teaching in China. He realized the majority of students he met knew a great deal about the United States, but that the same could not be said for American students’ knowledge of China. Upon his return he founded the institute with the hope that it would encourage Americans to learn more about China. Using $25,000 from the China Foundation, which administered the money China had paid as reparations for the Boxer Rebellion, Dewey, along with his student Hu Shih, who would go on to become a leader of the May Fourth Movement, started China Institute in New York.

It is the oldest bicultural organization in American devoted exclusively to China and houses one of the longest-running schools of Chinese studies in the United States. It teaches Chinese to children and adults, offers professional development opportunities for K–12 educators, develops K–12 curriculum, and promotes Chinese culture through its exhibitions and programs about traditional and contemporary Chinese arts and culture. It administers a number of overseas study opportunities for both teenagers and adults. The institute hosts in-house and traveling art exhibitions that are accompanied by scholarly expositions, curators’ lectures, and other programs that provide an in-depth background to Chinese art. In addition, the institute sponsors lecture series, short courses, symposia, film screenings, and workshops covering a range of traditional and contemporary topics, including history, literature, and philosophy.

The institute also provides executives from around the world with forums for networking and information sharing on critical issues in U.S.-China business relations, including an annual China Institute executive summit, regular panel discussions and speeches, and a corporate language program.

A Closer Look at John Dewey

In this brief biography of John Dewey, an American educator who was highly influential in China, his dedication to learning and to social change is apparent.

John Dewey was born in Burlington, Vermont, on October 20th 1859. After a period as a schoolteacher, he became a graduate student in philosophy at Johns Hopkins University, under the tutelage of the Idealist George S. Morris. With Morris, he left Johns Hopkins to take up a position at the University of Michigan. Dewey's early philosophical work was characterized by the attempt to combine the tenets of the Idealism imbibed from Morris with the emerging approach of experimental psychology to understanding the mind, exemplified by the work of another of Dewey's colleagues, G. Stanley Hall. Through the 1890s, and particularly after a move to the newly founded University of Chicago in 1894, Dewey began a steady drift away from Idealist metaphysics, a process that he describes in an autobiographical essay “From Absolutism to Experimentalism”...

...Dewey left Chicago in 1904 for the Columbia University, where he remained until his retirement. Dewey’s immense philosophical and other written output...extends over a long working life and encompasses most areas of philosophy as well as a host of other educational, social and political concerns. At the core of what may be called his “mature” outlook, expressed in his essay “The Need for a Recovery of Philosophy” (1917), is a concern that philosophy turns away from pseudo-problems in epistemology and metaphysics to concern itself with the “problems of men.” This was a proposal for the recovery of philosophy, not for its abandonment, and it is very much as a philosopher that Dewey approaches these problems, not (on the whole) as the architect of detailed institutional reforms.... Dewey’s interest in education was embedded in a wider concern about progressive social change. He was a supporter of such causes as women’s suffrage and the Settlement House movement of his friend Jane Addams. His immense range of public and political activities included presidency of the teachers’ union, sponsorship of the ACLU, support for the “Outlawry of War” movement in the interwar years, chairing the People’s Lobby, and (persuaded by his Sidney Hook) participation in the “trial” of Leon Trotsky in Mexico in 1938. After his move to New York, and particularly after the onset of the First World War, a substantial part of his published output consisted of commentary on current domestic and international politics, and public statements on behalf of many causes.

China National Radio (CNR) is the official radio system of the People’s Republic of China, with correspondent branches in forty cities. CNR is the farthest-reaching radio network in the country and one of the most important media organizations. Its nine channels of programming are under the editorial control of the Propaganda Department of the Chinese Communist Party Central Committee.

Established in 1940, China National Radio (CNR / 中国中央人民广播电台) is the official radio system of the People’s Republic of China, broadcasting 270 programs in nine channels, with 198 hours of daily broadcasting through satellites as of 2007. In 2002, CNR launched its website “CNR.CN” (www.cnr.cn), on which a nationwide broadcasting network of central and local radio stations was established to capture domestic and international audiences by providing news, entertainment, and other information-based programs.

CNR is the farthest-reaching radio network in the country and one of the most important media organizations. Administratively CNR is controlled by the National Bureau for Radio, Film, and Television within the State Council of China. Editorially it is controlled by the Propaganda Department of the Chinese Communist Party Central Committee.

CNR grew out of Yan’an Xinhua Broadcasting Station, which was established by the Chinese Communist Party as China’s first “Red” national radio in 1940 in the city of Yan’an, then the base of the Chinese Communist Party. In 1949 Yan’an Xinhua Broadcasting Station (renamed “Shanbei Xinhua Broadcasting Station” after it moved from Yan’an) began broadcasting in Beijing under the name of “Peiping [Beijing's former name] Xinhua Broadcasting Station.” On 5 December 1949 it was officially named “Central People’s Broadcasting Station.” Since January 2002 the station has been called “China National Radio,” with its acronym forming the basis for a website aimed at broadening its readership.

By 2007 CNR was broadcasting 270 programs in nine channels, with 198 hours of daily broadcasting through satellites. Channel 1 mainly transmits news in Mandarin to a national audience. Channel 2, Business Radio, airs economic, scientific, and technological information and service programs in Mandarin throughout China. Channel 3, Music Radio, is an FM stereo music channel. Channel 4, Metro Radio, provides live programs exclusively to listeners in Beijing. Channel 5 and Channel 6, Cross-Taiwan Strait Radio, aims its programming to listeners in Taiwan, while Channel 7, Huaxia Radio, broadcasts programs for listeners in Hong Kong, Macau, and the region of the Pearl River delta. Channel 8, Ethnic Minorities Radio, airs programs in Mongolian, Tibetan, Uygur, Kazakh, and Korean, and as well as in Mandarin. Channel 9, Story Radio, specializes in entertainment, including comic crosstalk and storytelling programs. After a recent reform CNR has increasingly stratified its programming to capture more specific target audiences.

CNR has forty correspondent branches in major Chinese cities, including Hong Kong and Macao, and has...
established cooperative relationships with major broadcasting organizations in forty foreign countries and regions. The new headquarters of CNR in Beijing, which opened in 1998, was a milestone in the organization’s transition to digitalization. The building houses world-class recording equipment, studios, and an eight-hundred-seat concert hall.

In the effort to become an integrated media organization, CNR has diversified its broadcasting-related services. It runs a publishing house, China Broadcasting Audio and Video Press, which produces several publications, including China Broadcast Weekly, China Broadcast Magazine (monthly), International Music Exchange (monthly), and Radio Songs. In addition, it has established its own TV-program production center. In 1998 CNR launched its official website, the first of its kind among the media organizations under the central government. On 1 January 2002 the website was officially named “CNR.CN” (www.cnr.cn), on which a nationwide broadcasting network of central and local radio stations was established to target domestic and international audiences by providing news, entertainment, and other information-based programs.

China-Britain Business Council

Yīng-Zhōng Màoyì Xiéhui 英中贸易协会

The China-Britain Business Council assists British companies and organizations doing business in China. The council operates through seven offices in the United Kingdom and a network of eleven cities in China.

The China-Britain Business Council (CBBC) is the leading British organization promoting trade and investment between the United Kingdom and China. The council’s history dates back to the early 1950s when British companies were among the first to establish trade with Communist China and became known as the “48 Group of Companies.” At the same time, the British government had a semiofficial trade body known as the “Sino-British Trade Council,” which promoted British participation in trade fairs and exhibitions in China. Despite these trade agreements, the U.K. did not officially recognize the People’s Republic of China until 1972.

The China-Britain Trade Group was established in 1991 when the 48 Group of Companies merged with the Sino-British Trade Council with the establishment of the U.K. Department of Trade and Industry. The organization changed its name to the “China-Britain Business Council” in 1998 to reflect the growth of business between the U.K. and China, which by that point encompassed investment, trade, licensing, and other forms of business.

The objective of CBBC is to assist any British company or organization to do business in China. It works in collaboration with U.K. Trade and Investment, for whom it delivers China business development services. CBBC also cooperates with the private sector and trade associations, the British Embassy and Consulate Generals in China, the British Chamber of Commerce in China, and other regional development agencies in the U.K. In addition, CBBC provides missions to the Chinese market, business opportunities, and research, as well as a range of services for companies in the marketplace. CBBC also hosts inward delegations from China, arranges events in the U.K. and China, and hosts business events for senior Chinese leaders visiting the U.K.

CBBC operates through seven offices in the U.K. and a network of eleven cities throughout China. The main office is in Beijing, and the other offices are located in Shanghai, Shenzhen, Wuhan, Chengdu, Qingdao, Nanjing, Hangzhou, Shenyang, Guangzhou and Chongqing.

CBBC relies on a bilingual and experienced staff and other organizations to provide business leaders with tailored advice and support in all aspects of setting up a presence and doing business in China. CBBC conducts smaller research projects through the Overseas Market Introduction Service for China and also provides in-house research services tailored to the needs of each company. All research is carried out by CBBC’s project managers across the China offices. CBBC has conducted research projects that encompass a wide range of sectors, including both product and service industries, and has processed a diverse variety of enquiries.

One of CBBC’s services, Launchpad, offers CBBC member companies a fast, cost-effective, and low-risk way to establish a presence in China by providing office space,
a dedicated CBBC project manager, and support in one of the CBBC China offices.

In 1978 after long and arduous negotiations, the China-Japan Peace and Friendship Treaty was ratified, setting a new tone of peaceful coexistence and mutually beneficial exchange of cultural ideas, economic goods, and technological advances between the two rivals, and simultaneously contributing to the security of the Asia-Pacific corridor.

After forty years of antagonism, China and Japan signed the China-Japan Peace and Friendship Treaty in Beijing on 12 August 1978. This treaty represented the turning point of Sino-Japanese relations, and its policies became the cornerstone of Chinese foreign policy.

Japan acknowledged the government in Beijing as China’s legitimate government in 1972 with the signing of the Sino-Japanese Joint Communiqué. Once diplomatic relations were therefore renewed, the path was opened for a treaty reflecting greater rapprochement, but it was not smooth going. Although negotiations began in November 1974, the treaty was not signed until four years later, in 1978.

The China-Japan Peace and Friendship Treaty actually addresses, to the greatest extent, political and economic relations, reflecting the principle of the Sino-Japanese Joint Communiqué and the essential principles of Chinese foreign policy. Article I of the peace treaty contains China’s Five Principles of Peaceful Coexistence:

- mutual respect for sovereignty and territorial integrity,
- mutual nonaggression,
- noninterference in each other’s internal affairs,
- equality and mutual benefit, and
- peaceful coexistence.

However, it does not address the two nations’ territorial dispute over the Diaoyu/Senkaku Islands in the East China Sea.

The China-Japan Peace and Friendship Treaty served to set the tone for friendly relations between China and Japan, to further cultural, economic, and technological exchange between the two nations, and to contribute to the overall security of the Asia-Pacific region. But many issues remain to be resolved in Sino-Japanese relations: territorial disputes (including the East China Sea dispute), visits to the Yasukuni Shrine, and differences in the recognition of history within junior high school history textbooks. The year 2008 represents the thirtieth anniversary of the China-Japan Peace and Friendship Treaty, and although issues between China and Japan flare up regularly, work continues on both sides to strengthen the Treaty and settle their cultural differences and differences in perspective.

Deng Xiaoping on the China-Japan Peace and Friendship Treaty

When Vice-Premier Deng Xiaoping visited Japan in October 1978 to attend the ratification ceremony of the Treaty of Peace and Friendship, he discussed the specific steps for implementing the Li-Komoto agreement in his meetings with Prime Minister Fukuda Takeo and other Japanese government and business leaders. At his Tokyo press conference, Deng declared:

We have signed a long-term trade agreement between the two countries. But just one such agreement is not enough. The total business turnover involved in this agreement is 20 billion U.S. dollars. It will be doubled or trebled. The road will be even broader when our country is developed. We have much to learn from Japan. There are many fields in which we can make use of Japanese scientific and technological achievements and even funds... It is only natural that with the conclusion and implementation of the China-Japan Peace and Friendship Treaty, cooperation between the two peoples will be strengthened. Cooperation between the two countries in political, economic, cultural and scientific fields will all be increased.

Chinatowns developed worldwide as Chinese immigrants settled to seek new lives abroad. Once considered ghettos for the poor, today’s Chinatowns are symbols of welcome cultural diversity.

Chinatown is a segregated community of Chinese immigrants. Chinatowns are located in many countries worldwide. The oldest are Japan’s Shinchimachi in Nagasaki, an enclave settled by Chinese traders as early as the seventeenth century, and Thailand’s two-century-old Chinatown in the area surrounding Yaowarat Road in Bangkok. Many Chinatowns originated during the mid-nineteenth century as Chinese fled the poverty and chaos of the late Qing dynasty (1644–1912) and sought to improve their lives abroad.

Chinatowns differ from segregated settlements or ghettos inhabited by Europeans living in Western countries because racial and cultural differences have made it more difficult for Chinese to assimilate. Moreover, in some countries, such as the United States, which had twenty-eight Chinatowns in 1940, Chinese were barred from citizenship and prohibited from property ownership until the mid-twentieth century. As a result, Chinatowns have continued to exist while many of their European counterparts have disappeared.
Early portrayals of Chinatowns were mostly negative, a phenomenon that often reflected tensions between Chinese and non-Chinese populations. Popular journals of the nineteenth and early twentieth centuries perpetuated the image of Chinatowns as repugnant. Common complaints included unsanitary conditions, overcrowding, unpleasant smells, and immoral or illegal activities. Chinatowns, especially in the West, became stereotyped as slum areas where opium smoking, gambling, prostitution, and gang activity flourished. In the United States such negative images helped fuel the passage of the Chinese Exclusion Act in 1882. That act barred immigration of Chinese laborers into the United States for ten years. The exclusion laws that resulted from the renewals and modifications of the original act were not repealed until World War II.

Recently the portrayals of Chinatowns have changed for the better; Chinatowns have become tourist attractions and examples of welcome cultural diversity in many countries. Sociologists have offered several explanations for the more appealing image. Since the 1960s Chinese in the United States and elsewhere have been characterized as an achievement-oriented minority group whose members have overcome discrimination and hardship to attain success. Pejorative terms such as insularity, clan-dominated, and old-fashioned have given way to positive terms such as industriousness, family pride, and self-respect. And yet a number of Chinatowns worldwide have been both victims and beneficiaries of urban renewal projects and stepped-up law enforcement: As urban property values rise and real-estate developers replace older housing with higher-priced buildings, the number of Chinese
residing in these neighborhoods has decreased—while the perception of safer Chinatown neighborhoods attracts non-Chinese to patronize their businesses. Many Chinatowns, such as London’s, have become primarily commercial areas where relatively few people live.

In many cities Chinatowns have been targeted for development projects that enhance their unique cultural traits so that they may serve as tourist attractions. Since 2000 cities such as Antwerp, Boston, Sydney, and Vancouver have preserved or built traditional Chinese-style gates and other landmarks setting their Chinatowns apart from other neighborhoods. Many Chinatowns today are residential and commercial centers that also try to preserve Chinese culture.

Chinese Central Television (CCTV, 中央电视台) is the official television broadcasting system of the Chinese government. Growing steadily since its trial broadcast in 1958, CCTV claimed to reach 94 percent of China’s population in 2008 with 16 channels and a daily total of 220 hours of programming. CCTV’s program content is heavily scrutinized by the Chinese government.

Chinese Central Television (CCTV) is the official television broadcasting system of the Chinese government, placed administratively under the National Bureau of Radio, Film, and Television within the State Council and editorially under the Propaganda Department of the Chinese Communist Party Central Committee. It is one of the most important media organizations of China.

CCTV began its trial broadcast on 1 May 1958 and began its official broadcast on 2 September 1958 as Beijing Television. In 1978 it was officially named “Chinese Central Television.” CCTV broadcasts on sixteen channels with a daily total of 220 hours of programming. Channel 1, a comprehensive channel, offers mainly news and other information-based programs. The other channels and their content are Channel 2, business; Channel 3, mixed entertainment programs; Channel 4, Mandarin broadcasts to an overseas audience; Channel 5, sports; Channel 6, movies; Channel 7, children’s, military, and agriculture; Channel 8, TV drama series; Channel 9, international broadcasts in English; Channel 10, science; Channel 11, theater; Channel 12, legal issues; Channel 13, news; Channel 14, children’s programming; Channel 15, music; and Channel 16, programs in French and Spanish. CCTV International was launched in September of 2000 and is an English-language twenty-four-hour news channel dedicated to reporting news and information to its global audience. Both Channels 4 and 9, with a special focus on China, are transmitted through satellites for audience overseas.

In addition, since 2003 CCTV has offered eleven pay channels that have even more diverse programming and are tailored toward special interests. CCTV also has twenty-eight channels of programs available online through its website (www.CCTV.com). CCTV’s estimate of its audience base in China is 1.1 billion.

Within CCTV’s structure are fifteen departments or centers responsible for various aspects of the TV system’s operation. In addition, CCTV owns China TV Drama Production Center (established in 1983), Central Documentary Production Studio (since 1993), and Beijing Science and Education Film Studio (created in 1995). CCTV also has its own TV program distribution center, China International Television Company (since 1984); Central Satellite TV Broadcasting Center (established in 1995); and China Philharmonic Orchestra (created in 2003). It also has its own publishing house, which publishes China Television, Television Studies, and Modern TV Technology. CCTV employs nearly ten thousand fulltime and part-time staff members.

Besides its claim to reach 94 percent of China’s population, CCTV has made an effort to capture audiences...
overseas. By 2007 it had established business relationships with more than two hundred TV stations in thirty-six countries. CCTV has fourteen foreign correspondent branches around the globe for international news coverage in addition to its extensive correspondent network in China.

CCTV’s new broadcasting center in Beijing, designed by the Dutch architect Rem Koolhaas and equipped with the most updated technology, was completed in 2008 and in operation in time for the 2008 Beijing Summer Olympics; this new facility has the capacity of broadcasting in two hundred channels. CCTV is the most steadily growing media organization in China, and its program content is heavily scrutinized by the Chinese government.

Communism spread to China from the Soviet Union in the years surrounding the demise of the Qing dynasty in 1912. The Chinese Communist Party was founded in 1921 by intellectuals Chen Duxiu (1879–1942) and Li Dazhao (1888–1927). Sending its rival, the Chinese Nationalist Party, into exile on Taiwan in 1949 after a four-year civil war, the Communist Party founded the People’s Republic of China and instituted massive socialist reforms with mixed success.

The Chinese Communist Party (CCP) was born from the infiltration of Western ideas into China at the end of the nineteenth and beginning of the twentieth century. After the Treaty of Versailles ceded Chinese territory to Japan at the end of World War I (despite China’s having participated in the war on the side of the Allies), Chinese students and intellectuals took to the streets in protest. During this time agents of the Comintern, the Soviet-dominated international Communist organization, agitated actively for the formation of a Chinese Communist Party, which they achieved in July 1921.

Early Days

In early 1920 the Communist International (Comintern) sent a young revolutionary organizer, Gregori Voitinsky (1893–1953), to China to establish a Chinese Communist party. Before he arrived the Soviet Union issued the Karakhan Declaration renouncing imperial Russia’s claims on China. This declaration set the Soviet Union apart from the West, which continued its exploitation, passing Germany’s concessions in China to Japan in the 1919 Treaty of Versailles, despite China’s having been an ally in World War I. As a consequence, many Chinese lost faith in Western ideals, and Voitinsky found a warm welcome.

Voitinsky helped Chinese intellectuals such as Li Dazhao and Chen Duxiu form Marxist study groups in Beijing, Shanghai, Changsha, Guangzhou (Canton), and Jinan. In the mid-1921 delegates representing about sixty members became the core of the Chinese Communist Party (CCP), committed to ending exploitation based on private ownership. Yet, the CCP was tiny, whereas the Chinese Nationalist Party (Guomindang [GMD]), led by Sun Yat-sen (1866–1925), was a growing revolutionary anti-imperialist party with an army. To promote
revolution, the Comintern pressed the CCP into an alliance with the Nationalists. The aim was for the CCP to help the GMD develop while simultaneously extending Communist influence to eventually make the Nationalist Party a Communist one.

The first period of GMD-CCP cooperation (the First United Front) ended in April 1927 when Chiang Kai-shek (1887–1975), commander of the GMD forces, turned on the Communists. Communist membership fell from fifty-eight thousand to four thousand active members, now experienced in organization, activism, and military and political affairs. While its urban influence evaporated, the CCP survived in the countryside, where, under Comintern direction, it instigated a series of failed uprisings, established worker-peasant-soldier soviets (councils), and implemented radical agrarian revolution, violently confiscating and redistributing land to the poor.

In October 1934 encirclement and attacks by GMD and local elite troops forced the CCP to flee the Chinese Soviet republic it had established in Jiangxi Province in southeastern China in November 1927. During this retreat, known as the “Long March,” Mao Zedong (1893–1976) rose to prominence. The threat of war with Japan allowed the Communists to portray themselves as patriots heroically advancing to fight Japan despite GMD resistance. Indeed, after Nationalist generals had kidnapped Chiang Kai-shek in Xi’an in 1936 the Communists intervened, urging the generals to spare Chiang’s life if he agreed to a GMD-CCP united front against Japan.

**From the Second United Front to Civil War**

In 1937 popular opinion and pressure from the Soviet Union forced the GMD and CCP into their second period
of cooperation, this time against Japan. This alliance formed half of the CCP’s Second United Front. The other half consisted of winning as many allies as possible among intellectuals, warlords, landlords, and others by making concessions in Communist ideology and practice. Mao justified these concessions by invoking the idea of “New Democracy,” a period of transition from the allegedly old “semi-feudal, semi-colonial” society to a socialist one. This transition would entail the long-term coexistence of different classes and forms of property ownership until the forces for the final transition to a classless socialism were strong enough. During this time all classes allied to the CCP would be represented in the political system. This policy was reflected in moderate policies including rent and interest-rate reductions rather than radical land confiscation and redistribution.

Inside its rural bases the CCP experimented with policies determined by local class structures and attitudes, GMD responses, rural conditions, attitudes of local elites, and international conditions. No overarching revolutionary theme of nationalism or land revolution existed to guarantee success for any one policy throughout China, although the CCP made much of its patriotism and worked hard to win support from the poor and landless in particular.

After the end of World War II in 1945, the CCP delayed civil war as long as possible, building military and political strength. Meanwhile, the GMD, racked by infighting and corruption, rapidly deteriorated. The GMD lacked a strong political and social base, while the economy suffered hyperinflation, further undermining the GMD’s legitimacy. Reviving the anti-CCP civil war cost the Guomindang more support, and its political weakness became increasingly obvious. The GMD was eventually defeated by CCP armies of rural soldiers won over by the promise of land, and by GMD deserters, disaffected students, and others who were promised a new China. The GMD fled to Taiwan in 1949.

**People’s Republic of China**

On 1 October 1949 Mao declared the founding of the People’s Republic of China. The CCP quickly moved to eliminate potential enemies, institute thought reform, confiscate many businesses, and implement land reform. The CCP subjected private businesses to repeated campaigns aimed at delegitimizing them and forcing them into state or cooperative ownership. Soviet-model rapid industrialization using central planning to develop state-owned enterprises was implemented according to five-year plans. Despite the Korean War (1950–1953), in which China was involved, the economy grew quickly. In 1956 Mao declared the transition to socialism complete and ended the “New Democracy.”

**Maoism**

Despite the apparent success Mao also saw increasing bureaucratism, dogmatism, and sectarianism in the CCP. Mao’s methods for rectifying these problems included allowing intellectuals to criticize government. Mao’s 1957 speech, “On the Correct Handling of Contradictions,” especially his line “Let a hundred flowers bloom and a hundred thoughts contend,” implied there was no more need for class struggle and reassured many that it was safe to speak up. However, Mao was shocked when his Hundred Flowers Movement, intended to encourage constructive criticism of CCP shortcomings, including criticism from the CCP’s United Front allies, also elicited severe criticisms of both the party and himself. In response he launched the Anti-Rightist Campaign. This campaign re-emphasized class struggle and encouraged anti-intellectualism. Mao promoted the use of big-character posters (in which propaganda slogans were broadcast in huge red pictographs), public meetings, and debates to force criticism and self-criticism—so-called big democracy. These methods often involved public humiliation and even torture of critics. Accusations of rightism could be spawned by denying the centrality of class struggle, advocating markets in economics, or opposing central planning or party control over politics and culture. Hundreds of thousands were labeled, exiled, imprisoned, demoted, and sidelined. These features of Maoism also marked the Great Leap Forward (1958–1960) and the Cultural Revolution (1966–1976).

The Great Leap Forward was an experiment by Mao to overcome the problems of central planning and to speed up industrialization. These goals were to be achieved by emphasizing mass mobilization, native ingenuity, and correct ideological viewpoint. Moral incentives rather than financial rewards were stressed, and distinctions between politics and technical knowledge were to be
eliminated to make individuals both “Red and expert.” Relying on surpluses from agriculture to fund industrialization, the Great Leap Forward accelerated the socialization and industrialization of agriculture by creating communes of up to five thousand households, where private plots, markets, and sideline businesses such as selling homemade pickled vegetables were eliminated. Decentralization and self-sufficiency were also key goals. The most famous Great Leap initiative was the building of “backyard” furnaces in communal settlements to raise steel output, but instead it created large amounts of unusable pig (crude) iron at enormous cost in labor, raw materials, and wasted resources. The CCP mobilized the masses to build rural infrastructure such as dams and irrigation projects. Unfortunately, poor planning, excessive state extraction of grain taxes, shortcomings in communes, and other problems, together with bad weather, resulted in an estimated 20 million deaths from starvation in rural areas.

After 1959, stung by the failure of the Great Leap Forward, Mao retreated from leadership. Pragmatic leaders, including Liu Shaopin (1898–1969) and Deng Xiaoping (1904–1997), then instituted moderate policies, allowed private plots and sidelines, and rehabilitated some alleged rightists. Mao saw this moderation as revisionism and betrayal of revolutionary ideals. He began building support in China’s army (the People’s Liberation Army) and in September 1962 asked everyone never to forget the class struggle. In 1964 Mao began to reimpose his will and ultimately created the Cultural Revolution.

Through the Great Proletarian Cultural Revolution, as it was officially named, Mao encouraged the army and students in particular to criticize those such as Liu and Deng, whom he saw as taking the capitalist road. Mao told students that rebellion is justified and that they should fight selfishness and criticize revisionism. CCP leaders and intellectuals such as teachers became targets of student Red Guards, who had prepared themselves by memorizing Mao zhuxi yulu (Quotations from Chairman Mao Zedong), nicknamed the “Little Red Book.” Many people, including Liu Shaopin, were tortured and died as a result. In line with Mao’s calls students also worked to destroy old ideology, culture, customs, and habits (the “four olds”). However, Mao’s egalitarianism also spurred the development of basic health care and education and attacked traditional elitism.

China and the CCP since Mao

The CCP now describes the Cultural Revolution as ten years of chaos and waste. After Mao’s death in September 1976 an interregnum existed under Chairman Hua Guofeng (b. 1921). The so-called Gang of Four (including Mao’s wife, Jiang Qing, 1914–1991) and others were arrested and blamed for the Cultural Revolution. In 1978 Zhao Ziyang (b. 1919) (tentatively) replaced Hua as China’s premier, but Deng Xiaoping came to wield the most power beginning in 1979 when he officially took over Hua’s position. The new leaders began rebuilding support among non-“Red” classes, especially intellectuals, former businesspeople, and those with overseas connections. The goals were the four modernizations (agriculture, industry, science and technology, and defense) and a dramatic increase in economic growth. Farmers benefited first when the communes were replaced with the household responsibility system, under which individual families again had responsibility for many decisions in the management of agriculture and rewards related directly to their success in production. The state increased produce prices and allowed the revival of private markets.

In 1980 Special Economic Zones (SEZs) were established in China’s south, where foreigners, overseas Chinese especially, could invest in manufacturing for export. After the SEZs proved successful, efforts to attract foreign investors spread widely. The state also began gradually relaxing controls on private business. Rural industries built by communes for self-reliance assisted rapid rural industrialization because their products could be sold at the revived rural markets or exported. Township and village enterprises (both village and privately owned) are now a major feature of the Chinese economy. State-owned enterprises have dramatically declined in importance and efficiency, and most are now heavily indebted and a drag on the economy. The CCP’s reform and opening-up policy marked a shift from autarky (self-sufficiency). The intent was not to abandon Communist ideals but rather to create socialism with Chinese characteristics, which proved itself by building national strength and raising living standards.

The changes created by reform have created major dilemmas for the CCP and its ideology. China is now a major economic power but only after abandoning most tenets of its original ideology and retreating from full
socialization of ownership to mixed ownership and markets. In 1987 Zhao Ziyang justified the CCP’s return to a New Democracy–type economy by declaring that China was in the initial stage of socialism and that full socialism could be achieved only when all the productive forces were fully developed and modernized. This formulation was reinforced by the 1992 promulgation of the concept of the socialist market economy, under which the declining state-owned sector coexists with cooperatives and foreign-owned and joint-venture businesses as well as, increasingly, Chinese privately owned enterprises.

In 1980 Deng Xiaoping had mooted major political reforms after blaming feudal and undemocratic traditions for the overconcentration of power in one person that had resulted in excesses such as the Cultural Revolution. Deng advocated a separation of the roles and powers of the CCP and government and called for more people’s democracy and debate in the party itself. A party theorist, Liao Gailong (b. 1919), promoted reforms, including direct elections at all levels and a two-house national parliament—one for regions and one representing economic interests—but with the CCP maintaining overall power. Deng’s ideas and Liao’s corporatist proposal were forgotten after the rise of Poland’s Solidarity trade union movement highlighted the threat of relaxing controls over mass movements by demonstrating how such movements could easily become dangerously politicized and threaten CCP rule.

A similar fate befell Zhao Ziyang’s modest late-1980s proposals to build socialist democracy—a broadening of representation and participation in the political system by new groups and experts in particular areas—by developing the national and lower-level People’s Congresses and by expanding United Front work and its public face, the Chinese People’s Political Consultative Conference. Whereas the congresses are elected and have nominal power to make decisions, conference representatives are

---

appointed. They can only review laws and policies and can make only recommendations to the government, the CCP, and public organizations. The student movement of April–June 1989, during which student demands for better living conditions, jobs, and less corruption, escalated to calls for an undefined democracy; the army violently suppressed the protests at Tiananmen Square on 4 June 1989. Zhao was sacked for his sympathy for the students’ demands, and his reforms were dropped.

Jiang Zemin (b. 1926), the PRC’s president from 1993 to 2003, endorsed upholding Deng Xiaoping’s four cardinal principles: the socialist path, proletarian dictatorship, leadership of the CCP, and Marxism-Leninism-Mao Zedong thought. While maintaining CCP dominance, these principles left little room for democratization. The party repeatedly campaigns against bourgeois liberalization (any calls for Western-style political reforms) and spiritual pollution while promoting construction of an ill-defined socialist spiritual civilization and nationalism as counterweights. In February 2000 Jiang began promoting the CCP as being the representative of advanced forces of production, of the fundamental interests of the broad masses, and of advanced culture. After 1987 incremental improvements were made in the local election process. Steady improvements have been made in China’s legal system but they have tended to focus on rule by law rather than on the idea of rule of law, something that is thought to be a better guarantee of the rights of Chinese citizens as written in the constitution. China’s accession to the World Trade Organization in 2001, its ever-increasing presence in international policy shaping, and its central role in the efforts to respond to the global economic crisis that began in 2008, tend to promote rule-based decision making.

The “eight immortals,” a group of older party members of the Chinese Communist Party who wielded power in China from the 1980s through 1990s. Top row, left to right: Deng Xiaoping, Chen Yun, Bo Yibo, Yang Shangkun. Bottom row, left to right: Song Renqiong, Peng Zhen, Wang Zhen, Li Xiannan.
During the last decade, the Chinese Communist Party has presided over a transition to a market-based economic system and seen an economic growth rate that has surpassed developed nations, such as the United States, Japan, and the European Union, while acquiring some $1.2 trillion in U.S. debt. It has done so while conscious of the urgent need to maintain social harmony by improving living standards.

The global economic crisis that began in 2008 presented the CCP with new challenges: It must deal with the plunge in China’s exports and the resulting job losses, and at the same time put a huge stimulus package into effect. By managing to contend with both these difficulties the party will make a significant contribution to the world economy.

Originally known as the “People’s Construction Bank of China,” the Chinese Construction Bank (CCB) is one of the big four banks in the People’s Republic of China (PRC) and has been making significant contributions to Chinese economic development for more than half a century, including the financing of such controversial projects as Three Gorges Dam construction.

Founded on 1 October 1954, the bank was wholly state owned under the direction of the Ministry of Finance of the People’s Republic of China (PRC) and in charge of administering and disbursing government funds for construction and infrastructure-related projects. For decades the bank had played a key role in the planned economy of mainland China.

In 1979 the People’s Construction Bank of China became a financial institution under the direction of the State Council and gradually assumed more commercial banking functions. In 1994, after the establishment of the China Development Bank, the People’s Construction Bank of China became a full-service commercial bank, and two years later its name was changed to Chinese Construction Bank. Since then it has become a leading commercial bank in China, providing a comprehensive range of services. As the bellwether in China’s financial reform, in late 2003 the State Council approved CCB’s application to become a shareholding bank. On 17 September 2004, Chinese Construction Bank Corporation was founded.

The year 2005 was important in the history of the bank. In March CCB Chairman Zhang Enzhao resigned for “personal reasons.” However, a lawsuit in the United States alleged that he received a bribe of $1 million from Alltel Information Services for securing a contract. Despite the negative publicity, the Bank of America decided to acquire a 9 percent stake in Chinese Construction Bank for $3 billion later that year. This measure represented the U.S. company’s largest foray into China’s growing banking sector. Bank of America was looking to greatly expand its Chinese business, which then had only branch offices in Hong Kong, Shanghai, and Guangzhou (Canton). On 27 October 2005, Chinese Construction Bank made an initial public offering on the Hong Kong Stock Exchange, and since February 2006 the share price has risen about 50 percent. In late 2007 CCB made China’s second-largest initial public offering of 57.12 billion yuan ($7.6 billion) on the Shanghai Stock Exchange.

Corporate Strategies

Chinese Construction Bank is currently among the market leaders in China in a number of products and services, including infrastructure loans, residential mortgages, and bankcards. Its core business consists of three principal segments: corporate banking, personal banking, and treasury operations. With the goal
of becoming a world-class bank, CCB has a corporate strategy of focusing on its customers, products, and geographical regions. The bank has strived to strengthen its historically strong relationships with large corporate customers by focusing on leaders in strategic industries such as power, telecommunications, oil and gas, and infrastructure, as well as major financial institutions and government agencies, and by developing relationships with small- and medium-enterprise customers. In the personal banking segment CCB seeks to increase revenues from high-income retail customers while capitalizing on its cost efficiency and economy of scale to serve mass-market customers more efficiently. In terms of its services, CCB has developed both wholesale and retail products with a focus on fee-based businesses, including payment and settlement services, personal-wealth management, and corporate-treasury management. In light of high savings rates and a booming real estate market in China, CCB also endeavors to increase its personal banking business with a focus on residential mortgages, diverse savings products, and an industry-leading credit card business. Its geographical focus is in the major cities of the more developed markets of the Yangzi (Chang) River delta, Pearl River delta, and Bohai Rim regions. In addition, the company has an ambitious goal of growth in the capital cities of inland provinces in China. CCB has already built an extensive customer base and established relationships with many of the largest business groups and leading companies in industries that are strategically important to China’s fast-growing economy. Its network includes approximately thirteen thousand branch outlets.

**International Expansion**

During recent years CCB has also expanded internationally. The bank is a member of the Global ATM Alliance, a joint venture of several major international banks that allows customers of the banks to use their ATM card or check card at another bank in the Global ATM Alliance with no fees when traveling internationally. In addition, CCB maintains overseas branch operations in Hong Kong, Singapore, Frankfurt, Johannesburg, Tokyo, and Seoul and has representative offices in New York and London. In 2006 CCB acquired Bank of America (Asia), which started in 1912 in Hong Kong as Bank of Canton with a subsidiary in Macao. After the acquisition Bank of America (Asia) became the Chinese Construction Bank (Asia) Corporation. CCB’s other subsidiaries include Chinese Construction Bank (Asia) Limited (formerly Jian Sing Bank Limited), Sino-German Bansparkasse Co., and Chinese Construction Bank Principal Asset Management Co. In 2007 *Fortune* magazine ranked CCB at 230 on its Global 500 List (CCB had previously ranked 277). Within the banking sector CCB is ranked 34, with annual revenue of more than $28.5 billion.

The Chinese Nationalist Party (Guomindang), which began as a parliamentary party in 1912, has seen three major eras (from 1912 to 1927, 1927 to 1978, and 1978 to the present) in which the party leadership, its objects, and its strategies have changed dramatically—in both China and Taiwan. It is currently in the unfamiliar position of opposition party to the Democratic Progressive Party.

The Chinese Nationalist Party (Guomindang), which began as a parliamentary party in 1912, has lived through three major eras. The Nationalists' role, as well as their strategy and goals, has shifted dramatically within each era.

During the first era (1912–1927) Sun Yat-sen (1866–1925) led the party until his death. He made major adjustments in the Nationalists' goals and structure because of domestic warlordism and competing foreign interests in China. Sun set forth the Nationalists' philosophy, the Three Principles of the People, but had little success in the contest for political power. Sun's loyal military commander, Chiang Kai-shek (1887–1975), assumed command of the party in 1927 and established the Republic of China in the Nationalists' second era (1927–1978). His dominance lasted in spite of dramatic shifts in Nationalist fortunes until his death. Even though the Nationalists lost the Chinese Civil War (1946–1949) to the Chinese Communists, Chiang Kai-shek managed to reestablish a Nationalist Party–led Republic of China on Taiwan. Thus, the Nationalist Party completely dominated the Republic of China both in China and on Taiwan from 1927 until 2000, when the Democratic Progressive Party (DPP) came to power in the Republic of China on Taiwan well into the third era of party history, which began in 1978).

After establishing the Republic of China at Nanjing in 1927 the Nationalists enjoyed a decade of relative peace. Then, in spite of Nationalist efforts to postpone a war, the Japanese invaded China and began a long, debilitating struggle from 1937 to 1945. Following Japan's defeat, the weakened Nationalist Party lost control to the Chinese Communists in a civil war ending in 1949. The Communists, under the leadership of Mao Zedong (1893–1976), established a new People's Republic of China (PRC). With Chiang Kai-shek still in command, the Nationalist Party and the Republic of China, still inseparable, withdrew to Taiwan. Chiang Kai-shek established a dictatorial state ruling under martial law and pledged to retake the Chinese mainland. After his death the Nationalists entered their third era. Leadership passed to Chiang's son, Jian Jingguo (Chiang Ching-kuo) (1910–1988). Beginning in 1975 the party slowly moved away from its revanchist (relating to a political policy designed to recover lost territory or status) goals to emphasize economic development and popular democracy in Taiwan. The Nationalists as a party and the people of Taiwan all prospered during these years. However, in 2000 the Nationalists lost political control of the government to a Taiwanese party, the Democratic Progressive Party. The Nationalists thus became the chief opposition party in a two-party political...
system on Taiwan. Since then the party has pinned its hopes on regaining control through regular democratic elections.

**First Era, 1912–1927**

After the fall of the Qing dynasty (1644–1912) in 1912, Sun Yat-sen envisioned China as a modern national state governed through a parliament and representative government. To that end Sun advocated that his umbrella anti-Manchu coalition known as the Tongmenghui (Revolutionary Alliance) be transformed into a parliamentary party, the Nationalists. The heart of the Tongmenghui was its opposition to the rule of the Manchus and the advocacy of a new government that would be led by Chinese. The Tongmenghui involved garnering support from various groups: radical revolutionaries who wanted to assassinate the Manchu leaders, simple patriots, businessmen hoping for a modern economic system, advocates of parliamentary democracy, promoters of provincial self-rule, champions of militarized China, and non-Marxist socialists and anarchists. This dream quickly faded because Sun had no real office in the new government, and General Yuan Shikai (1859–1916), the first president, had the Nationalist parliamentary leader Song Jiaoren (1882–1913) assassinated. Beginning in 1913 Sun tried a number of means to gain power including armed revolution; creation of the secret Revolutionary Party (Gemindang), in which members signed a loyalty oath to Sun himself; alignment with progressive warlords; and courting of Japan, England, and the United States for aid. In 1917 Sun established Guangzhou (Canton) as his base and revived the Nationalist Party as an organization. The warlord Chen Jiongming (1878–1933), distrustful of Sun, expelled the Nationalists from Guangzhou in 1922. After a decade of the Republic of China, Sun and the Nationalist Party seemed doomed to more failures.

This prospect changed in January 1923 with a formal alliance between the Nationalists and the Soviet Communist International. Behind the scenes Sun Yat-sen had courted Soviet interest and support from 1920 as the newly victorious Bolshevik Revolution in Russia began reaching out for allies in the colonialist world. Sun began borrowing from the Marxist-Leninist program. He adopted Marxist anti-Western, anti-Japanese rhetoric as well as efforts to organize Chinese workers and peasants. Sun also accepted members of the fledgling Chinese Communist Party into the Nationalist Party. The Soviets sent military advisors and equipment. Sun made an impressive and loyal military officer, Chiang Kai-shek, head of a new military academy just outside Guangzhou. As the Nationalists’ prospects brightened Sun promoted the Northern Expedition, in which armed forces would combine with workers and peasant uprisings to rid China of warlordism. The Nationalist Party would then establish a genuine Republic of China at Nanjing.

In these same years Sun made a number of modifications in his famous Three Principles of the People—nationalism, democracy, and people’s livelihood. Sun’s
ideas about nationalism initially had focused on the Han Chinese majority in the former Qing empire but evolved into a concept of a multinational polity filling all the territory ruled by the Manchus, including Mongolia and Tibet. For Sun democracy originally meant a representative government elected by popular vote and operating under a constitution. He always believed that the Nationalists would need to exercise tutelage for years during which the party educated the Chinese people about democracy. His experience in the decade after 1912 led him to extend this period of tutelage indefinitely. The concept of tutelage opened the door for the Nationalists to assume authoritarian powers. People’s livelihood always seemed an amorphous principle linked most closely to traditional Chinese concepts that the state should foster the well-being of its subjects. As a consequence of Soviet influence, people’s livelihood in the early 1920s came more clearly to reflect Marxist socialism and to be modeled on the Soviet state-managed economic order.

Pancreatic cancer took Sun Yat-sen’s life in March 1925 before the Northern Expedition could be launched. A period of disorder in the party leadership followed his death. Wang Jingwei (1883–1944), a confidant of Sun who embraced Sun’s anti-imperialist, class warfare views,

Franklin D. Roosevelt, Chiang, Kai-shek, and Winston Churchill in Cairo, Egypt, 25 November 1943. Chiang assumed command of the Nationalist Party in 1927. Despite dramatic shifts in Nationalist fortunes throughout the various contexts of war with Japan, and after defeat in the civil war by the Communists, Chiang’s dominance in the party lasted until his death. NATIONAL ARCHIVES.
was a contender. At the time, most people believed that Chiang Kai-shek, the loyal commander of the Nationalist military, also supported this leftist, pro-Soviet position. More conservative Nationalist Party members created their own rump party in Beijing and denounced the Communist influence at Guangzhou. However, Chiang Kai-shek, who had visited the USSR and had not liked what he had seen, began revealing his distrust of the Soviets in March 1926, a few months before launching the Northern Expedition.

The Northern Expedition, led by Chiang Kai-shek, began in July 1926 with full support of the Soviet advisors and the leftist elements in the Nationalist Party. It won impressive early victories even while fracturing into left and right wings. The leftists, including the Soviet advisors, the Chinese Communist leadership, and Wang Jingwei, based themselves in Wuhan, while Chiang Kai-shek took Nanjing and then Shanghai. On 12 April 1927 Chiang Kai-shek, with assistance from Shanghai underworld gangs, attacked the Communists and the Shanghai labor movement, decisively severing his previous association with the pro-Soviet elements in the Nationalist Party.

Within months Soviet leader Joseph Stalin (1879–1953) recalled the Soviet advisors to Moscow, the Communist Party carried out abortive peasant uprisings, and the leftist headquarters at Wuhan collapsed. Chiang Kai-shek made opportunistic alliances with northern warlords and set up a Nationalist Party state at Nanjing that won international diplomatic recognition. China appeared to have ended the warlord disorder, to have turned away from the Soviet Union, and to have taken a path friendly to capitalism.

**Second Era, 1927–1978**

The year 1927 ushered in an era of peace and economic construction in Nationalist history called the “Nanjing Decade.” The Nationalists maintained firm control of policy under the rubric of Sun Yat-sen’s principle of tutelage. All hints of radical Soviet-style land reform and other Marxist socialist policies disappeared. Chiang Kai-shek and his advisors favored state capitalism in which government-owned enterprises controlled the manufacture of major capital and military goods, while other state-sponsored corporations dominated trade in the chief commodities. Private businesses continued to operate, but the Nanjing bureaucracy determined much of their destinies.

In fact, Chiang Kai-shek’s rule rested on his ability to manage a number of factional elements within the Nationalist Party. He proved adept at this game while organizing loyal young followers in a “Blue Shirt” organization while trumpeting the New Life Movement to improve public behavior and morals. Chiang Kai-shek himself was presented as a remote but concerned father/ruler in the Confucian mode. The Nationalists were copying qualities of Italian, Spanish, and German fascism.

The Nationalist government in Nanjing worked for two major domestic goals. First, Chiang Kai-shek wanted to destroy the Chinese Communists once and for all. Second, he wanted to reduce the autonomy and military capacity of the remaining warlords in China. To do this Chiang Kai-shek needed to build up his military strength with larger, better-equipped armies. He turned to Germany, the Soviet Union, and the United States for military supplies and advice.

Chiang Kai-shek, who had received his military education in Japan, understood that the Japanese presented the greatest challenge to the Nationalist government through their policies of military expansion in China. Expansionist and aggressive Japanese policies rested on a conviction that Japan’s own success at modernization entitled it to leadership throughout Asia. Japanese ruling circles rejected the Anglo-U.S. view that Chiang Kai-shek was the new leader of a united China. Instead they saw him as a regional warlord who wrapped himself in Sun Yat-sen’s impractical political ideas.

Beginning with the takeover of Manchuria in 1931, waves of Japanese military aggression against China heightened nationalistic resistance in the Chinese public. Chiang Kai-shek and the Nationalist government placed their struggle against domestic enemies first. This policy led to the Chinese Communist–supported kidnapping of Chiang Kai-shek at Xi’an in December 1936 in hopes of turning attention to Japan’s aggression. This so-called Xi’an Incident produced a temporary revival. Undeclared war broke out in June 1937, and the Japanese drove the Nationalist government out of its strongest regional base in the lower Yangzi (Chang) River valley and into isolation in the Sichuan basin. Chiang Kai-shek remained in control, but the Nationalist Party splintered with Wang
Jingwei breaking away in 1940 to set up a rump Nationalist government in Nanjing under Japanese auspices.

The United States stepped up its support for the Nationalist government even before the Japanese attack on Pearl Harbor in 1941, but the twin effects of fighting against the Japanese and suffering runaway inflation ate away at the Nationalists in the early 1940s. When World War II ended in August 1945 Chiang Kai-shek attempted to assert Nationalist control throughout China, but even with U.S. assistance he failed. A civil war broke out between the Nationalist government and the Chinese Communists. The Nationalists’ apparent advantages evaporated quickly, and their government collapsed in the autumn of 1949.

A sizable remnant of the Nationalist armed forces, including much of the air force and navy, withdrew to Taiwan. Taiwan had become a Chinese colony in 1895 but was returned to Chinese control after World War II. The first occupying Nationalist army had carried out a repressive occupation, and thus there was no real welcome for the fleeing Nationalists when they arrived 1949–1950. Loss of the Chinese mainland obviously is a critical turning point in Nationalist Party history, but the continuation of Chiang Kai-shek and Nationalist Party domination of the Republic of China makes these years all one era.

The future of Chiang and the Nationalists as rulers of Taiwan appeared bleak until the outbreak of the Korean War in June 1950. From that point on the Nationalist government received generous economic and military support from the United States as part of U.S. strategy in the Cold War. Chiang himself continued to dream of returning to the Chinese mainland and expelling the Communists. The Nationalist government and military on Taiwan lived by that dream but never received sufficient support from the United States to attempt a full-scale invasion.

On Taiwan the Nationalists ruled through martial law but maintained a façade of representative government through a 1947 constitution and an elected parliament. It still paid homage to Sun Yat-sen and his Three Principles of the People as its guiding philosophy. A major land reform was undertaken with impressive results in increased production and diversification. The Republic of China remained the internationally recognized government of China until 1973, when, after U.S. President Richard Nixon’s visit to Beijing, the People’s Republic of China replaced the Republic of China in the United Nations. Chiang Kai-shek’s dreams for the party came to an end with his death in April 1975.

**Third Era, 1978 to Present**

Chiang Kai-shek’s son, Jiang Jingguo (1910–1988), had been appointed premier in 1972 and became president in 1978. He began the third era of the Nationalist Party with the appearance of continuing his father’s policies. It seemed that Chiang Kai-shek’s authoritarian style would continue to prevail. In fact, a major economic transformation had already begun through efforts to promote medium- and small-scale production for export to U.S. and Japanese markets. The Taiwan economy prospered. Individual households became wealthier, and the Nationalist Party itself became rich through its ownership of many businesses. The party used its wealth to buy support for its regime. During the decade of Jiang Jingguo’s leadership he loosened the Nationalists’ grip on political power. A key indicator was the election of representatives to the Taiwan provincial legislature who did not follow the Nationalist Party line.

Upon Jiang Jingguo’s death leadership of the party passed to Li Donghui (Lee Teng-hui, b. 1923), a native Taiwanese educated in Japan and the United States. Under his control the long period of Nationalist Party tutelage finally ended. Li proclaimed a goal of full democracy in 1990. Martial law was rescinded in 1991. A popularly elected national legislature replaced a body dominated by a 1947 election on the Chinese mainland. Politics became much more open, but the influence of money and corruption increased. Li Donghui became the first popularly elected president of the Republic of China in 1996. In this period the Democratic Progressive Party, a Taiwanese-based party advocating a Taiwanese identity separate from China, became a real rival to the Nationalists.

Sun Yat-sen’s Three Principles of the People remained enshrined as the official ideology in the Republic of China. No one is sure if “nationalism” refers to a pan-Chinese notion or should be a Taiwanese notion. Democracy has proven to be a messy but still enormously absorbing means of political rule. People’s livelihood seems to have been achieved but through a much more capitalistic form than Sun Yat-sen advocated.

In the elections of 2000 the DPP won control of the legislature, and its candidate, Chen Shuibian (b. 1950), won the presidency. This election put Nationalists in the role of an opposition party for the first time since 1927. Stung by the defeat and fearful that the DPP would openly declare independence from China and bring about a military confrontation with the People's Republic of China, the Nationalist Party turned on Li Donghui and expelled him for what they considered to be his underhanded advancement of Taiwanese independence.

In the unfamiliar role of an opposition political party the Nationalists advocated less-confrontational policies with Beijing. Chen Shuibian and the DPP became strident advocates of Taiwanese independence from China and claim the Nationalists are inclined to compromise and accept eventual unification with the People's Republic of China. In March 2008 the electorate in Taiwan, unhappy with the DPP leadership and policies, turned back to the Nationalist Party. Ma Yingjiu (Ma Ying-jeou) (b. 1950) defeated Chen Shuibian in the Presidential race, thus returning the leadership of the Republic of China to the Nationalist Party.

Chinese, Classical

Wényánwén 文言文

Classical Chinese refers to the formal written language of China prior to the twentieth century, a terse, learned language of the educated distinct from the spoken vernacular of the masses. Following the Vernacular Language Movement of the 1910s, writing in China shifted to vernacular Chinese, but remnants of the classical language survive in modern writings in the form of allusions, idioms, and set expression.

Classical Chinese refers to the language of established literature and formal writings in China before the twentieth century. In the early twentieth century, language reforms were instituted so that writing was no longer carried out in the classical language, which was understood by only an educated elite, but instead done in an approximation of the modern vernacular (everyday language) of the north.

The expression Classical Chinese has a narrow and a broad sense. In its narrow sense, Classical Chinese (gūwen, ancient text) is the designation for written language from the Zhou dynasty (1045–256 BCE) through the Han dynasty (206 BCE–220 CE), encompasing the language of the Chinese classics and early historical narratives. Later imitations of the classical style, used in literature and formal writings from the third century to the early twentieth century, are referred to as Literary Chinese (wényanwén, literary text). The classical/literary divide is in many ways similar to the relationship between Classical Latin and Medieval Latin, both learned languages. In actual usage, however, the classical/literary distinction is not always maintained by Chinese academics, as gūwen and wényanwén are used interchangeably to refer to formal writing styles before the advent of modern literature (baihuawén, plain speech text).

When attempting to frame a formal definition of Classical Chinese, linguists tend to resort to one of two strategies. The first is to treat Classical Chinese as all that is not vernacular writing—definition by default. The second is to pinpoint the historical period out of which Classical Chinese writing developed and state that Classical Chinese consists of literary traditions that grew out of the speech habits of a particular time and place.

The Classical/Vernacular Divide

Criteria that have been traditionally used to distinguish Classical and Vernacular Chinese include the following:

1. **Intelligibility**: Is the text readily understood by the average native speaker, or is the language comprehensible only to an educated elite?
2. **Spoken versus written mode**: Does the text resemble natural speech, or is it more characteristic of stylized writing?
3. **Time depth**: When speaking of natural speech and average native speaker, are we using present-day speakers as a reference point?
Intelligibility means that the language is comprehensible to a general audience. If it cannot be understood by the average native speaker without further training, it is considered unintelligible. Vernacular Chinese (baihua, plain speech) is Chinese written in language the average speaker can understand. Everything else is classified as Classical Chinese regardless of the source. This view is often reflected in popular comments about writing styles. Certain styles are difficult to understand because they are too wenyan (classical/literary). In this view Classical Chinese stands for all writing styles understood by only a few.

There are problems with this approach, however. The first is that intelligibility judgments are limited to the here and now, for there is no way of determining whether people in ancient times could understand a particular style of writing. We are tied to the judgments of a modern audience. If we were to do this, we run into a second problem, which is that we would have to exclude from our definition of Vernacular Chinese the language of popular historical novels such as Outlaws of the Marsh (Shuihu Zhuan) and Dream of the Red Chamber (Honglou Meng), which are traditionally considered vernacular literature (baihua xi-aoshuo) but are in modern times not fully comprehensible to the uneducated reader.

An alternative to the intelligibility criterion is that of language mode: spoken language versus written language. Most of the world’s languages maintain a distinction between spoken and written modes. The spoken mode is usually more informal and involved, employing more first- and second-person pronouns (I, you), conjunctions (and, but), and situation-dependent references (last night, over here), whereas the written mode tends to be more informational, abstract, and explicit, often containing learned or technical vocabulary. Relying on such universal tendencies, we can determine whether the text at hand is closer to typical spoken language or written language. Texts that resemble spoken language are then labeled Vernacular Chinese. Those with attributes of written language are relegated to Classical Chinese.

Written language. It is not the case that uneducated speakers can only understand language in the spoken mode, and find formal writing entirely unintelligible. There is an area of overlap where language can have characteristics of the written register, and is yet comprehensible to the uneducated reader.

Whether we use intelligibility or spoken/written mode as criterion, however, an additional variable is time depth, the historical period of the intended audience. Writing that is intelligible to or characteristic of the population of one historical period may be unintelligible to or uncharacteristic of the speech of another stage in history. For this reason it is important to specify the period on which we are to base our definition.

Chen Duxiu, one of the founders of Communism in China, was both a scholar and a rebel. He and his fellow intellectual Hu Shi succeeded in bringing about the Vernacular Movement, or the change from writing in a Classical Chinese to a colloquial syntax.
A definition of Classical Chinese based on spoken/written mode from the perspective of a historical audience was given by scholar Hu Shi (1891–1962), who was one of the chief proponents of language reform and vernacular writing in early Republican China. In his influential work Baihua Wenxue Shi (A History of Vernacular Literature, 1928), Hu described a division in which vernacular literature is literature written in the spoken language of the day (which may be far removed from the spoken language of today), and classical literature is all other literature. By this definition what is vernacular and what is classical is not a fixed notion, but rather varies with each historical period. Hu’s definition, while similar to the European notion of vernacular and mainstream literature, is actually foreign to the Chinese tradition. Hu is often criticized for framing a definition of vernacular language that is too broad. His definition would necessarily include obscure works of oral literature from remote periods, which speakers of Modern Chinese have great trouble understanding.

A more widely accepted definition of Vernacular and Classical Chinese is that of Lü Shuxiang (1944, 12), which states that vernacular literature is written text that corresponds to spoken language from the Tang dynasty (618–907 CE) onwards. All else is relegated to Classical Chinese. Lü’s treatment avoids the shortcomings of both Hu’s working definition and the layman’s notion of the vernacular. It includes drama and popular writing from

Gates to the Altar of Heaven, within the Temple of Heaven complex, Beijing. Built in 1530 (Ming dynasty) and enlarged in 1749. Ming and Qing dynasty emperors offered prayers on this altar to the “Great Spirit Who Resides in Heaven” at the time of the winter solstice. If emperors (or their imperial scholar-officials) had written out their prayers it would have been in Classical Chinese, the language of established literature and formal writings in China before the twentieth century. PHOTO BY JOAN LEBOLD COHEN.
the Ming (1368–1644) and Qing (1644–1912) dynasties while excluding obscure pre-Tang works of oral literature. Lü’s definition is sometimes criticized for its arbitrary choice of the Tang dynasty as a divide, but it is worth noting that the intermingling of Sinitic and Altaic-speaking populations in cosmopolitan Tang society accounts for the considerable linguistic gap between Middle Chinese (265–1269) and Premodern Chinese (1269–1795). It is also during this period that basic Chinese word order began to shift from subject–verb–object to subject–object–verb—a change often taken to be an important distinction between Classical Chinese and Modern Chinese.

A number of linguistic features distinguish Modern Chinese from its classical predecessor. Whereas Modern Chinese acquired a system of stress and rhythm that led to the development of longer words, vocabulary in the classical period consisted by and large of single-syllable word forms. In the classical language, words can easily change from noun to verb or adjective and vice versa, whereas in the modern language such flexibility is rare. When counting objects, nouns in Modern Chinese are always preceded by a measure word—not so in Classical Chinese. Classical Chinese does not require a “to be” verb, and its pronouns and articles are significantly different from those of modern day usage.

Classical Chinese, as an abstract form of writing far removed from the Chinese spoken language, was an East Asian lingua franca readily borrowed by neighboring states. It was in wide circulation outside of China proper, often existing as an elite written language alongside the local vernacular, similar to the use of Latin in Western Europe. Up until the twentieth century, the educated classes in Japan, Korea, and Vietnam possessed a reading knowledge of Classical Chinese (known as kanbun in Japanese and hammun in Korean). Being a semantic (related to meaning) rather than phonetic (related to sound) means of representation, Classical Chinese did not have a uniform pronunciation but instead was incorporated into the pronunciation system of the local language or dialect.

Classical Chinese through the Ages

Some scholars believe that the classical writing style may have been derived from the spoken language of an earlier period. Linguists have found considerable overlap between Classical Chinese grammar and the syntax of Old Chinese oracle bone and bronze inscriptions of the Shang (1766–1045 BCE) and Western Zhou (1045–771 BCE) dynasties. The inscriptions are for the most part short sentences describing ceremonies and divinations, and are considered a more or less faithful record of the spoken language of the day in the Huang (Yellow) River basin.

With the breakup of the Zhou empire (1111–256 BCE), a new culture of pluralism demanded a more stylized form of writing suited to political oratory. This is reflected in the language of works such as the Confucian Analects (Lunyu) and Mencius (Mengzi), which shows obvious imitations of earlier classics and is more concise and structured, and richer in rhetorical devices.

Writing during the later Warring States period (475–221 BCE) and the Qin (221–206 BCE) and Han dynasties saw a further move toward allegory and ornamentation, resulting in a style distinct from the vernacular language of the day. It was during this period that Classical Chinese forged an identity as a literary language separate from vernacular speech, and it is the conventions of this period that later authors sought to emulate when writing in the “classical style.” For this reason some sinologists reserve the term Classical Chinese (guwen) for the writings of the Zhou, Qin, and Han dynasties and refer to the language of later imitations as Literary Chinese (wenyanwen).

Following the Han dynasty, worship of form was taken to an extreme at the expense of substance, giving rise to the parallel prose (pianwen) of the Southern dynasties (420–589 CE), in which balance of rhythm, imagery, and tonal patterns became the focus. This worship of formal elements created a backlash in the Tang dynasty, in which neoclassicists such as Han Yü (768–824 CE) and Liu Zongyuan (773–819 CE) called for a return to substance and the rhetorical styles of the Zhou, Qin, and Han dynasties. From the Tang dynasty onward, different schools of writing have offered different takes on the classical language, and literary aesthetics have swung back and forth between form and substance, and between arch conservatism and the adoption of new grammars and lexicons.

The dominance of Classical Chinese started to wane after the Opium War (1840–1842), as intellectuals began to see the classical/vernacular gap as a hindrance to greater literacy and called for the replacement of Classical Chinese with the modern spoken language in education.
and media as part of the modernization of China. In the New Culture Movement of the late 1910s, promotion of Vernacular Chinese gathered momentum through the efforts of noted scholars such as Hu Shi, Chen Duxiu (1879–1942), Qian Xuantong (1887–1939), and Fu Sinian (1896–1950), culminating in the Vernacular Language Movement (Baihuawen Yundong) of 1917–1919. The success of the movement led to the adoption of Vernacular Chinese as the language of textbooks, and influential new works of literature by authors such as Lu Xun (1881–1936) began appearing in the vernacular.

To this day, however, the classical language lives on in government notices and legal documents and in all manner of writing deemed formal. Classical patterns and set expressions appear frequently in vernacular prose—more so in Taiwan and Hong Kong than in mainland China. Despite the efforts of early twentieth-century language reformers to make a clean break with wenyan, it looks as though it will be some time before the new writing born of the Vernacular Language Movement can forge an identity fully distinct from that of the classical language that has been standard for much of Chinese history.

The Chinese-American Networking Symposium (CANS) is held annually as a forum for leaders in networking and applications research and development. It offers a forum in which to exchange information and to promote partnerships between Chinese and U.S. institutions, both from the private and public sector. The theme of the 2008 meeting encapsulates the symposium’s goals: “One world, one network.”

Participants of the Chinese-American Networking Symposium (CANS), an annual networking forum, include faculty, students and professional staff from leading universities and research centers, government agencies, and the private sector from both the United States and China. CANS sessions are designed to promote collaborative partnerships in network research and across scientific and academic disciplines. Alternating yearly between U.S. and Chinese venues, the symposium includes presentations by networking experts and disciplinary researchers, panel discussions, and parallel technical and non-technical (executive) sessions.

The Chinese-American Networking Symposium was initiated in 1998 by Donald R. Riley, of the University of Maryland College Park, and Xiao Shuigen, of the Chinese Association for Science and Technology, USA (CAST-USA), in partnership with the China Education and Research Network (CERNET) and the China Science and Technology Network (CSTNET, Chinese Academy of Sciences). The first symposium was held in Washington, D.C., in January 1999 with more than fifty executives, network industry leaders, and officials from China, and more than sixty participants from the United States. Chinese attendees represented the education and research community and the major Internet service providers in China: CERNET, CSTNET, China Commercial Network (ChinaNet), and representatives from the Ministry of Education, Ministry of Information Industries, Chinese Academy of Sciences, and some local Chinese governments.

Technical topics have focused on the traditional advanced networking research and infrastructure development issues that have been integral to CANS and remain important but have evolved to include higher-level subjects: infrastructure development and especially Open International Exchange Points (a network hub facility to which any international research and engineering [R&E] network may connect and also interconnect to other international R&E networks to exchange network traffic); the complexities of international network interoperability and routing issues; Internet protocol version 6 (IPv6) development; middleware (computer software that connects software components and deals with network interface and security issues); technical aspects of grids; and e-science and research collaboration support. Each CANS symposium also offers cultural experiences for the attendees.
Today CANS is sponsored by Internet2 (a nonprofit consortium that develops advanced network technologies for research and education in the U.S.), CERNET, CSTNET, and CAST-USA. The CANS Council and Organizing Committee sets the direction and oversees the planning of each CANS meeting. The CANS Council includes co-founder Riley, as well as representatives of the four sponsors, plus a representative from the U.S. National Science Foundation.

CANS highlights have included:

- Signing of the international collaboration agreement between Internet2, CERNET, CSTNET, and NSFCNET (Natural Science Foundation of China Network).
- Collaboration of CSTNET with the University of Tennessee on the Global Ring Network for Advanced Application Development (GLORIAD) project funded under the National Science Foundation International Research Network Connections (NSF IRNC) program. GLORIAD is a multi-gigabit-per-second global ring that initially connected the United States, Korea, China, and Russia and then NORDUNET (a collaboration between Nordic national R&E networks) and SURFNET (Samenwerkende Universitaire Reken Faciliteiten, the Dutch national R&E network).
- Collaboration of CERNET with Indiana University and Internet2 on the TRANSPAC2 project funded under the NSF IRNC program.

TRANSPAC2 provides multi-gigabit-per-second connectivity from the United States to CERNET and members of the Asia-Pacific Advanced Network (APAN).

Such interoperable high-performance network connections enable many scientific and educational collaborations between the United States and China. And CANS has played an important role as a neutral forum for initiating and strengthening the human interactions and cultural exchanges needed for scientific, educational and technical collaborations.

Chinggis Khan was a tribal leader in the late twelfth and early thirteenth centuries. He first united Mongolia, then conquered northern China and much of central Asia. The Mongol empire eventually stretched from the Pacific Ocean to the Adriatic Sea.

Chinggis Khan, meaning “resolute leader” (sometimes spelled “Genghis Khan”) was born with the name “Temujin.” Although scholars are not certain of his birth year, the country of Mongolia has accepted 1162, although 1165 and 1167 also have been viewed as reasonable. Temujin, after surviving tribal wars in Mongolia after the death of his father, Yesugei, built a tribal confederation that radically restructured Mongolia. After gaining power in 1185 Temujin suffered numerous setbacks and eventually victories. Among these was the kidnapping of his wife, Borte, by the Merkit tribe. Although Temujin eventually got her back, almost a year had passed and Borte was pregnant. Although Temujin accepted Jochi (d. 1225), as the child was named, scholars have little doubt that Jochi was fathered by a Merkit. His ancestry later became an issue in determining a successor to Temujin.

Temujin was able to recapture Borte only with the help of Toghril Ong-Khan (d. 1204), ruler of the powerful Kereit confederation and the former blood brother of Yesugei. During his time with Toghril, Temujin also learned...
the arts of war from Temujin’s blood brother, Jamuqa (d. 1205–1206). However, Temujin’s relationship with Toghril and Jamuqa eventually soured. Rivalry between Jamuqa and Temujin for leadership of the Mongols led to a clash. Although Jamuqa won the battle in 1187, Temujin won the war as more Mongols flocked to support him because of his charisma as a social revolutionary. Temujin increasingly implemented laws that, although not favoring the lower classes, made tribal life more egalitarian rather than simply favoring the aristocrats, as Jamuqa had. One example was a more equitable distribution of the plunder from battles.

Temujin returned as a major force in the steppe (one of the vast, usually level and treeless tracts in southeastern Europe or Asia) in 1195. After his return he slowly accumulated power in eastern Mongolia by defeating rival tribes. Although his relationship with Toghril seems to have protected him from further feuds with Jamuqa, Temujin eventually clashed with his overlord. Toghril, who seems to have viewed Temujin as a potential successor, led his armies against Temujin at the urging of Jamuqa and Toghril’s children, who feared that they would lose power after Toghril died. In 1203 Temujin defeated the Kereits, thus also gaining ascendancy over central Mongolia. In 1204 he defeated the Naiman and Merkit tribes in western Mongolia. By 1206 Temujin was the dominant power in Mongolia and received the title “Chinggis Khan.” The years between 1185 and 1206 were the most difficult years for one of the most respected but feared men in history.

**The Desire for Stability**

After uniting the tribes of Mongolia into the Mongol supratribes, Chinggis Khan conquered much of northern China and central Asia. He launched his invasions not to rule the world but rather to maintain stability in
Mongolia. His concerns stemmed from the fact that although he had unified Mongolia, many tribal rivalries continued. If other tribes were left to their own devices, warfare could easily break out. Thus, by sending them to raid in China, he reduced the threat to Mongolia. In addition, the sedentary states bordering Mongolia had a long history of intervening in Mongolia for their own motives, primarily to prevent one tribe from becoming too powerful. Chinggis Khan’s rise to power in the early 1200s seems to have happened too quickly for any of the sedentary rulers to react to it. Nonetheless, because Chinggis Khan had lived in northern China after his defeat by Jamuqa, he probably understood Chinese policies toward the steppe tribes. The raids thus also prevented the Chinese states from meddling in the steppe because they now had to defend themselves.

In 1209 the Uygurs voluntarily submitted to Chinggis Khan. Later that year the Mongols began their conquest of the Tangut kingdom of Xi Xia, located in China’s northwestern Gansu Province. After the Tanguts submitted in 1210, hostilities flared between Chinggis Khan and China’s Jurchen Jin dynasty (1125–1234). Although the Jin were not defeated until seven years after Chinggis Khan died, the Mongols conquered much of northern China during his lifetime.

Chinggis Khan led his forces toward central Asia in 1219 after a Mongol-sponsored caravan was massacred in the Khwarazmian empire (consisting roughly of modern-day Uzbekistan, Kyrgyzstan, Tajikistan, Turkmenistan, Afghanistan, part of Pakistan, and Iran). In fighting with the Khwarazmian empire, the Mongols devastated most of central Asia and eastern Iran. After routing the Khwarazmians the Mongols withdrew to deal with their disobedient vassal Xi Xia, which had refused to send troops for the campaign in central Asia. During this campaign Chinggis Khan died from internal injuries suffered after he fell from his horse while hunting in August 1227.

Historical illustration of “Merchants offering their Goods” at one of Chinggis Khan’s encampments. From Ghengis Khan by Jacob Abbott. Even after his death the Mongol armies dominated the battlefield until the empire stretched from the Pacific Ocean to the Adriatic Sea.
The wars of Chinggis Khan were motivated as often by retaliation as by greed for territory or riches. His strategic and organizational genius created one of the most highly disciplined and effective armies in history, but that same genius created the core administration that ruled that army. Even after his death the Mongol armies dominated the battlefield until the empire stretched from the Pacific Ocean to the Adriatic Sea.

**Nonmilitary Achievements**

Chinggis Khan's nonmilitary achievements include the introduction of a writing system to the Mongols, the ideal of religious tolerance throughout his empire, and unity among the Mongols. His accomplishments cannot be counted in terms of territory or victories but rather in the presence of a Mongol nation and culture. Mongols still venerate him as the founding father of Mongolia, naming airports, hotels, streets, universities, and banks after him.

Chongqing
Chóngqìng 重庆
31.4 million est. 2006 pop.

Chongqing Municipality is the largest of four province-level municipalities in China (the others are Beijing, Shanghai, and Tianjin). Chongqing City is the largest city in Chongqing Municipality. Modern-day Chongqing, municipality and city, is one of the fastest growing and dynamic regions in the country; it is one of the main industrial centers in southwest China.

Chongqing (also known as Yu and formerly as Chung King), is the largest of four province-level municipalities in China. A municipality is not the same as a city; it encompasses urban areas, suburbs, and surrounding farmland and wilderness. Chongqing City, with a population of 5 million, is the largest city in the municipality and an important river port. Chongqing Municipality is one of the main industrial centers in southwest China. Also, with its rich natural resources, its favorable location, and its potential for development, Chongqing Municipality is one of the fastest growing regions in the country.

Landscape
Chongqing Municipality runs from latitude 28 degrees north (roughly the latitude of Tampa/St. Petersburg, Florida) to 32 degrees north (roughly the latitude of Savannah, Georgia), about 450 kilometers (280 miles). From east to west, it stretches some 470 kilometers (292 miles) between longitudes 105 and 110 east. The municipality covers 82,300 square kilometers (31,776 square miles), roughly the size of South Carolina. Chongqing shares borders with the provinces of Hunan to the southeast, Guizhou to the south, Sichuan to the west, Shaanxi to the north, and Hubei to the east. Along the Chongqing–Hubei border the Yangzi (Chang) River cuts through Mount Wushan to form the famous Three Gorges.

The climate is subtropical, with extremely hot summers (Chongqing City is known as the “Furnace City”), mild winters, and two monsoon seasons. It has an annual rainfall of 1,000–1,400 millimeters (39–55 inches). The area is quite foggy and humid year round. Rain in late spring and early summer usually falls at night, making the city famous for its night rain in the Ba Mountains.

The Chongqing region is mountainous and crisscrossed with springs and rivers—most notably the Yangzi and Jialing rivers—and dotted with caves and gorges. Chongqing City is very hilly and the only major city in China without a lot of bicycles. More than 20 percent of the region is forested, with many species of harvestable trees, along with a number of rare indigenous species protected by the state.

Natural Resources
The area is also rich in mineral resources. Chongqing Municipality is a major producer of coal, manganese, mercury, aluminum, vanadium, molybdenum, barium,
and strontium, along with natural gas. Chongqing also produces nonmetal minerals such as rock salt, barite, fluorspar, limestone, and silicon. The area is also rich in underground thermal energy and drinkable mineral water.

The Yangzi River runs through the municipality. The Yangzi is joined by the Jialing, Qujiang, Fujiang, Wujiang, and Daning rivers and hundreds of streams to make the municipality one of the most important in China for actual and potential hydropower. In 1994 the central government began work to control the Yangzi with the ambitious but controversial Three Gorges Dam project.

Three Gorges Dam

East of Chongqing City the Yangzi cuts through the limestone Wushan Mountains to form the celebrated Three Gorges: Qutang, Wuxia, and Xiling. The river then spills over the Yangzi Plain at Yichang and continues its course to the Pacific Ocean. At 6,276 kilometers (3,900 miles), the Yangzi is China’s longest river and the third longest in the world, behind the Nile and Amazon. The watershed created by the great river covers 19 percent of China’s total landmass.

The Three Gorges Dam is the world’s largest hydroelectric project and the biggest engineering project in China since the Great Wall. When the dam reaches full operational capacity in 2009, twenty-six generators will produce some 8,200 megawatts of power, enough to meet almost 10 percent of China’s requirements. It will be the largest source of clean, renewable energy in the world.

But the damming of the river has drowned fertile farmland and destroyed settlements of the ancient Ba people. Many artifacts were also lost although archaeologists were able to save some, which now reside in the Three Gorges Museum in central Chongqing City. The dam project has also forced the relocation of 1.3 million people at a cost of more than 45 billion yuan ($6.5 billion). In 2007, because of instability problems with newly formed land, the Chongqing Municipality government relocated an additional 4 million people.

Cultural Resources

The people of Chongqing Municipality are said to be straightforward, enthusiastic, and generous yet somewhat rustic. The majority of the people of the municipality are Han, but people from forty-nine minority groups also live in the municipality, mainly in rural areas. The population of the minority groups is about 1.75 million, or 5.6 percent of Chongqing’s total of 31.4 million. The Tujia people are the largest minority group, at 1.13 million, followed by the Miao at 520,000. The other groups include Mongolians, Tibetans, and Koreans. Mandarin is the principal language. Only about 20 percent of the population lives in urban areas. Sichuan is the main cooking style, with variations of the hotpot one of the most popular dishes.

Chongqing Municipality is rich in traditional Chinese culture and performing arts. Chongqing City alone boasts of twelve museums and memorial halls, including the Chongqing Museum, the Hongyan Memorial Hall of Revolution, and the Geleshan Revolutionary Martyrs Tomb. Traditional performing arts have a strong folk-art flavor, with some 3,000 arts organizations and twenty-nine professional troupes in the area. Two local performance groups have won international acclaim. The Chongqing Artistic Troupe combines acrobatics with traditional folk music and Chinese opera. The Chongqing Municipal Acrobatics Troupe, formed in 1951, performs traditional martial arts, juggling, and acrobatics. Its artists are famous for their juggling bowls while on an unbalanced teeterboard routine. The troupe has won many international acrobatics competitions. A popular street scene is groups of older citizens dancing for exercise, instead of practicing the art of Tai Chi, which is so common throughout China.
Chongqing Municipality is also noted for its historic sites. There are about fifty national, provincial, and municipal preservation sites. These include the Shi Bao Zhai tower, a twelve-story temple built in the eighteenth century; the Ba hanging coffins, ancient burial sites in and along rock formations; and the Dazu Rock Carvings, a collective name for some 50,000 carved and sculpted religious figures, created between 665 and 1249, at seventy-five sites.

History

Human activity in the locale now called Chongqing Municipality goes back to the end of the Old Stone Age, 20,000 to 30,000 years ago. When the Zhou dynasty (1045–256 BCE) replaced the Shang dynasty (1766–1045 BCE), the Ba people established their state with present-day Chongqing City as its capital. The city was known first as Jiangzhou and then Ba Prefecture. During the North and South dynasties (220–580 CE), it was renamed Chu Prefecture. During the Ming (1368–1644) and Qing (1644–1912) dynasties, Chongqing City became an important trading, transportation, and industrial center and the link between southwest China and the upper Yangzi River with the rest of the world. In 1891 it was declared an open port, and a customs house was established there.

In 1929 Chongqing was officially established as a city. In 1939 it was elevated to the status of municipality. From 1940 to 1946, it served as the wartime provisional capital for the Nationalist government and became China’s political, economic, financial, commercial, transportation, and cultural center. When the Nationalist government returned to its former capital, Nanjing, in 1946, Chongqing was returned to its position as a municipality.

In the early years of the People’s Republic of China, Chongqing served as the seat of the Southwest Bureau of the Communist Party of China Central Committee, the seat of the Southwest Military and Administrative Commission, and the political, economic, and cultural center of southwest China. It functioned as a municipality directly under the central government until 1954 when its official status was changed again to a city, under the government of Sichuan Province. This last change was part of a nationwide administrative reorganization. In the 1950s Chongqing City became a center for trade. In addition, bridges and railways were built in southwest China, making Chongqing an important transportation hub connecting railways from the west to the far cheaper river transport to the east.

Chongqing City’s star continued to rise after the opening of China in 1979. In 1981 it became China’s first inland port opened to the outside world. Over the next several years, it became an official foreign port, a designated model city for market economics to attract foreign investments, the first pilot city to test a comprehensive reform of China’s economic system, and the first city at the provincial level granted the authority to manage its own economic affairs. In the 1980s Chongqing was given jurisdiction over the cities of Wanxian and Fuling, and the Qianjiang Prefecture. Finally, on 14 March 1997, Chongqing became China’s fourth direct-controlled municipality and the only one in western China, thus opening a new chapter in its long history.

Administration

Direct-controlled municipalities are the highest level cities under China’s administrative structure. Their status is equal to that of provinces. The municipalities are enclaves, culturally and ethnically distinct from the territory and people that surround them. They occupy strategic positions within or between provinces. There are three other municipalities besides Chongqing in the People’s Republic of China: Beijing, Tianjin, and Shanghai. Chongqing is divided into thirteen districts, six counties, five autonomous counties, and sixteen county-level cities.

Chongqing City and its environs is also one of the main industrial centers in southwest China, with such heavy industries as iron works and steel mills. There are many factories for the manufacture of motorcycles, cars, heavy machinery, electronic equipment, chemicals, and textiles, and for the processing of food, farm products, and timber. The city is the largest port along the Yangzi
River and the transportation and communication hub of southwest China. Chongqing Municipality is rich in natural resources and natural beauty, attracting a steady stream of tourists from China and around the world. Since ancient times, the area has been known as the Land of Abundance.

The Chongyang Festival dates from a legend first described in the fifth century CE, in which a magician warns a young scholar to get his family to higher ground on the ninth day of the ninth month to avoid calamity.

The Chongyang Festival is also known as “Deng-gao Jie” (Mountain Climbing Festival) and “Juhua Jie” (Chrysanthemum Festival) after the major activity or item involved in the event. The festival falls on the ninth day of the ninth lunar month—hence the name chongyang (double nine). On that day people old and young climb mountains or high ground, taking with them chrysanthemum wine and sweet flour fruit cake and wearing dogwood leaves (Evodia rutaecarpa) on their heads or arms. In Chinese folk medicine chrysanthemum wine has the ability to lower blood pressure and thus extend life.

In Chinese folk belief chrysanthemum, whose yellow color is similar to that of sulfur, has the ability to ward off ghosts or evil spirits. Likewise, in Chinese folk medicine, dogwood leaf is used to prevent mosquitoes and to treat cholera. Thus, people who leave congested cities for high mountains in early autumn and take along food that has medicinal uses have health considerations in mind, as do those who attend the Dragon Boat Festival on the fifth day of the fifth lunar month.

Scholars generally believe that the Chongyang Festival was a post–Han dynasty (206 BCE–220 CE) development. The earliest record of the festival is in a book, Xu Qixieji (续齐谐记), compiled by Wu Jun in 460–450 CE. According to legend, Huan Jing, a young scholar, once studied under a famous magician, Fei Changfang, for several years. One day Fei warned Huan, “Your family would face major calamity on the ninth day of the ninth month. You should go home and bring your family members to high grounds on that day. Tie dogwood leaves on their arms and ask them to drink chrysanthemum wine. This would prevent the disaster from happening to your entire family” (Bodde 1977, 69). Huan followed his master’s advice and rushed home. He took all the members of his family to a nearby mountain on the morning of the ninth day of the ninth lunar month. They carried chrysanthemum wine in bottles and dogwood leaves on their arms. At dusk when they returned to their farmhouse, they found that all the domestic animals, including dogs, oxen, sheep, goats, and fowl, had died of unknown causes. It is said that ever since that time, people have followed this practice of climbing mountains or high ground on that day, carrying the specified wine and foods.

The late professor Wolfram Eberhard believed that the Chongyang Festival, similar to Zhong Qiu (Moon Festival), was not originally a Han Chinese festival. It was, he believed, a festival belonging to the Yue people who once lived widely scattered in south China’s Fujian and Guangdong provinces but who now live mainly in Vietnam. As agriculturalists, the Yue people celebrated the completion of their harvest by hiking up the mountains to avoid the dangers lurking in the valleys.

Chopsticks

Kuài zi 筷子

There have been many tales about the emergence of chopsticks and the evolution of their names. Chopsticks have been made in various materials and with diverse artistic styles, and numerous etiquettes are involved in their use. Disposable chopsticks have become an environmental concern today.

By tradition, silverware is the choice eating utensil of Europeans and Americans; the hand is the preference of Indians, Indonesians, and people of the Middle East; and chopsticks are the favorite of Chinese, Japanese, Koreans, and Vietnamese.

Chopsticks are a pair of tapered sticks of even length. The Chinese word for chopsticks is kuài or kuài zi 筷子. Kuài is a phono-semantic compound (characters linked together to indicate a related meaning and a sound), the character for quick 快 indicating its pronunciation and the radical for bamboo 竹 hinting at the major material of its making. The word chopstick seems to come from Cantonese Pidgin English chop chop (quick, quick 快快).

The Chinese name for chopsticks has changed over time. Originally known as jia 蒯 (to hold), the utensil assumed the name zhu 竹 around the Qin–Han period (221 BCE–220 CE). Zhu, however, is homophonous (having the same pronunciation) as stop 止 or bore 蚧 (by insects). The Chinese, especially those who boated in the south, considered the word unlucky and replaced it with a word sounding like kuài 快, a homophone of quick, sometime during the Qing Dynasty (1644–1912).

Chopsticks are made primarily of wood and bamboo, though ivory chopsticks are said to have existed some 3,000 years ago, and royal families and aristocrats preferred silver ones, believing in the metal’s capacity to detect arsenic. Today chopsticks can be made of coral, jade, silk, plastic, horn, porcelain, animal bone, and stainless steel. Since the Song Dynasty (960–1279), artistic designs have become part of chopsticks. Dream of the Red Mansion, a classic of Chinese literature written in 1754, depicts a pair of ebony chopsticks decorated with sections of silver inlays.

The origin of chopsticks is unknown, but it must be closely related with the Chinese diet and cooking methods. Chinese eat grains as staple food, supplementing them with vegetables and meat. They cut the vegetables and meat to convenient sizes before cooking, and it would be hard to pick them up from hot soup with bare hands. A pair of improvised twigs may have led the early Chinese to create chopsticks. Later, as vessels like bowls became light enough to be held in one hand, chopsticks became useful for shoving rice and small pieces of food into one’s mouth.

Legends about the origin of chopsticks abound. One recounts Jiang Ziya, a legendary figure of the Western Zhou dynasty (1045–771 BCE). A magic bird gave him a pair of bamboo twigs capable of revealing poison to save him from his murderous wife. Another story tells that Da Yi, a concubine of King Zhou of the Shang dynasty (1766–1045 BCE), fed him with her hairpins when she found the food was too hot for her hand. Still another story recounts that Yu, a flood-fighting hero of the Emperors Yao and Shun period, which predated the Xia dynasty.
A pair of chopsticks decorated with cloisonné enamel, and held in the traditional manner. Diners in Westernized Chinese restaurants, used to paper-wrapped disposable chopsticks, might be surprised to see chopsticks so fancifully embellished—and either intimidated or amused by the formal etiquette surrounding their use. Do not, for instance, point them at people, or allow sauces to drip from them, or use them by their wrong ends, or rest them upright in a bowl of rice. PHOTO BY ANNA MYERS.

(2100–1766 BCE), was too busy to wait for his food to cool, so he fished it out of boiling soup with a pair of twigs he broke from a tree.

Many rules of etiquette govern the proper use of chopsticks. The following acts are considered bad manners: laying them in a disorderly fashion on the table; pointing them at people; sucking the tips; allowing sauces to drip from them; using them by their wrong ends; resting them upright in a bowl of rice; dropping them onto the floor; beating them on a surface like drumsticks; and using them to pierce food or to poke around looking for a particular item in a dish. To avoid smearing the tablecloth at formal dinners, people often place chopsticks on small rests of porcelain or glass specially crafted for the sticks.

For hygienic reasons China began using disposable chopsticks from Japan in the 1980s. Today China uses 45 billion pairs of disposable chopsticks a year, equaling 1,660,000 cubic meters (2,169,935 cubic yards) of timber. Appeals are being made for supplementing bamboo for wood and encouraging people to bring their own chopsticks when they go out to eat. As of 1 April 2006 China levied a 5 percent tax on disposable wooden chopsticks in an effort to cut down on their use.

Giblin, J. (1987). From hand to mouth, or, How we invented knives, forks, spoons, and chopsticks, & the table manners to go with them. New York: Crowell.

Christianity in China remained for several centuries a marginal, foreign religion that attracted relatively few converts. Missionaries and Chinese Christians were considered a threat to the political and social order in late imperial, republican, and early Communist China. Anti-Christian agitation and conflict were not uncommon. In recent decades the authorities have permitted a degree of religious freedom, thus enabling the remarkable expansion of Christianity.

The first reliable evidence of Christian missionary activity in China is found on a famous monument—erected in Chang’an (now Xi’an) in Shaanxi Province in 781 CE and rediscovered in 1625. The Chinese and Syriac inscriptions state that a certain Alopen arrived in the capital of the Tang dynasty (618–907 CE) in 635. Alopen, a member of the Church of the East (called “Nestorianism” by some), translated The Sutra of Jesus the Messiah, borrowing the vocabulary from Buddhist and Daoist concepts. It became the first Christian book in Chinese. The eastward spread of the Church of the East from Persia (Iran) along the old Silk Roads to China occurred at a time of remarkable religious tolerance and cultural openness. However, after these auspicious beginnings, the Church of the East began to decline in China soon after the erection of the monument. When the Tang dynasty was overthrown in 907, China’s first Christian church vanished in the chaos that followed.

The Mongol expansion in Asia created the conditions for the reappearance of Christianity in China. The pragmatic policy of religious toleration of Khubilai Khan, founder of the Yuan dynasty (1279–1368) in China, enabled the Church of the East to make a comeback. The Mongol world empire also facilitated direct contacts between east Asians and Europeans. In 1287 the Nestorian monk Rabban Sauma, an Önggüt Turk who was born in what now is Beijing, was sent on an embassy to Europe. He visited Rome, Paris, and Bordeaux, meeting the pope and the kings of France and England.

The favorable conditions of the Yuan dynasty also allowed Roman Catholicism to enter China. Pope Innocent IV and other European rulers conceived the idea of an alliance with Mongols against Islam. Several fact-finding missions were sent to the Mongols. However, the missions of the Franciscan monks Plano Carpini (1245–1247), William of Rubruck (1253), and others to the East were unsuccessful. Not until the arrival of the Franciscan friar John of Montecorvino in Khanbaliq (or Dadu, present-day Beijing) in 1294 was Western Christianity able to establish a foothold. John was permitted to build a church in Beijing in 1299. In a letter written in 1305, he reported some six thousand converts. In recognition of these achievements Pope Clement V appointed him archbishop of Cambaluc (Khanbaliq) and patriarch of the east. Subsequently a Catholic presence was established in other places. By the time the Franciscans Odoric of Pordenone (around 1322) and John of Marignolli (1342) arrived in China, the Yuan dynasty was already in decline, to be overthrown in 1368.
In the next year all Christians were expelled from Beijing. Once again Christianity disappeared with the fall of a dynasty. The new isolationist Ming dynasty (1368–1644) would not tolerate foreigners and their religions, whether Catholic or Nestorian.

**Planting Christianity in Late Imperial China**

The Jesuit Francis Xavier, having evangelized in Japan, hoped to begin work among the populous Chinese as well. However, he died in 1552 on Shangchuan Island (St. John’s Island) off the coast of southern China before he could reach his goal. The first two Jesuit missionaries who successfully entered the Chinese empire in 1583 were the Italians Matteo Ricci (1552–1610) and Michele Ruggieri (1543–1607). After a number of false starts they were invited by the prefect of Zhaoqing near Guangzhou (Canton) to reside in his city. Between 1589 and 1601 Ricci traveled and established a number of missions in some cities of central China. Finally, in 1601 he was permitted to go to Beijing, the imperial capital. The years from 1601 until his death in 1610 mark the peak of Ricci’s achievement, setting the pattern of activity for the Jesuit mission in late imperial China.

In order to gain the respect of the Chinese ruling class (scholars and officials), Ricci and his Jesuit successors studied the Confucian classics. At the same time they strove to impress the Chinese elite with Western achievements in the fields of astronomy, mathematics, and mechanical skills (instruments and clocks) to convince

Church spires rise between buildings. Figures are uncertain, but it may be reasonable to accept the latest estimate of 53 million—mainly unregistered—Christians in China, of which 39 million are Protestants and 14 million are Catholics. PHOTO BY BERKSHIRE PUBLISHING.
them that the Europeans were no mere barbarians. This approach brought them to the attention of well-known scholars, high-ranking officials, and even some of the emperors. Because of their scientific knowledge, some Jesuits were retained by the imperial court as quasi-officials. Having gained the intellectual respect of the Chinese elite, the early Jesuit missionaries began to propagate their religion. Ricci in particular sought to avoid unnecessary conflict with Chinese tradition and questions of dogma by interpreting the terms used in Chinese classic texts as elements of Christian doctrine when doing so would be appropriate. By this means the Jesuits showed their willingness to accommodate and had limited success in converting some important scholar-officials, most notably Paulus Xu Guangqi (1562–1633).

After the Manchu conquest of China in 1644, a number of Jesuit missionaries were retained in imperial service by the new Qing dynasty (1644–1912) in Beijing. Johann Adam Schall von Bell (1592–1666) acted as director of the Astronomical Bureau. His successor, Ferdinand Verbiest (1623–1688), was able to gain the attention of the great Kangxi emperor (reigned 1662–1722). Indeed, the emperor’s attitude toward Catholicism during the middle years of his reign can be regarded as one of “positive neutrality,” culminating in the promulgation of the so-called Edict of Toleration in 1692. Yet soon afterward the situation of the missionary enterprise in China became increasingly precarious.

**Rites Controversy and Its Consequences**

The exclusive position of the Society of Jesus (Jesuits) in China had been undermined since the 1630s with the arrival of Dominicans, Franciscans, and priests of the Paris Foreign Mission Society (MEP). These missionaries worked primarily among the common people in the provinces. Here they came face to face with Chinese popular religion, with its pantheon of popular deities and the ubiquitous ancestor worship and geomancy (feng shui). Whereas the court Jesuits had adopted a tolerant attitude toward Chinese rites, the provincial missionaries denounced them as superstitious practices. Consequently the protracted “Rites Controversy” caused considerable disagreement within the missionary community. Another controversial issue within the missionary community concerned the nature and rendering of “God” in Chinese. Eventually the term Tianzhu (Lord of Heaven) was adopted, and Catholic Christianity henceforth became known as Tianzhujiao, the religion of the Lord of Heaven.

Because the Kangxi emperor was supporting the Jesuits, Pope Clement X sent a papal legate to China in 1704 to present the opposite position, forbidding Christians to take part in sacrifices to Confucius or to ancestors. Offended by this papal interference, the emperor issued an order that all missionaries, in order to obtain a permit (piao) to remain in China, would have to declare that they were going to follow “the rules of Matteo Ricci” in their activities. The decision of Pope Clement XI in 1715 to rule against the Jesuit compromise did not help matters. The ruling was finalized in 1742 by Pope Benedict XIV in the papal bull Ex quo singulari. The refusal by Rome to allow Christians to take part in the Confucian and ancestral rites was to have grave consequences because Chinese converts were cut off from the Confucian cultural tradition and thereby from society at large.

In 1724 the Yongzheng emperor issued an edict proscribing Christianity. Christians were commanded to renounce their faith, and foreign missionaries, except those attached to the Bureau of Astronomy in Beijing, were expelled from China. Church properties were confiscated and used for secular purposes. For the next 120 years Christianity was officially proscribed as a heterodox (contrary to or different from an established religion) and subversive cult. Catholicism retreated into the remoter parts of rural China, increasingly vulnerable to persecution. The papal abolition of the Society of Jesus in 1773 aggravated the precarious position of Christianity. The few remaining priests (Chinese and European), operating secretly in the country, provided rather inadequate pastoral supervision.

In the absence of regular priestly care, many Chinese Christians were left to their own devices for years if not decades. In any case, successful evangelization had from the beginning depended on the generous assistance of native converts. In spite of the many vexations and periodic persecutions, Chinese laypeople, especially the so-called institute of virgins, were instrumental in preserving the
faith. Some 200,000 Christians are said to have existed nationwide in scattered communities at the beginning of the nineteenth century. These congregations of “old Christians” formed the vital bases from which the next phase of Catholic expansion would be launched in China.

**From Mission to Church in Modern China**

The religious revivals in Europe and North America at the end of the nineteenth and beginning of the early twentieth centuries engendered renewed missionary interest in China. However, the Chinese people remained suspicious of and hostile toward the foreign religion, and missionary activities continued to be illegal and precarious. Not until after the opium wars and the imposition of the so-called unequal treaties was the propagation of Christianity greatly facilitated. The most important concessions were gained by the missionaries in the treaties of 1858–1860. These treaties permitted travel and evangelization anywhere in the interior of China. Particularly noteworthy here is the French treaty (especially the notorious Article VI of the 1860 Beijing Convention, containing surreptitiously inserted additional rights in the Chinese version), permitting the purchase of land and erection of churches anywhere in the country. Associated agreements exempted Catholics from contributing to communal endeavors that were thought to have a “superstitious” component. Most important, the French government assumed a religious protectorate over all Catholics in the Qing empire, including foreign missionaries regardless of nationality as well as Chinese converts.

The arrival of Protestant missionaries, starting with Robert Morrison of the London Missionary Society in 1807, added a new dimension after 1800. Prior to the treaties these missionaries were confined to Macao and seasonal residence in Guangzhou. In both locations their religious activities were severely restricted. The Treaty of Nanjing (1842) enabled the Protestants, mostly from the United States and Britain, to establish themselves in the newly opened five treaty ports and Hong Kong. After 1860 the Protestant missionary presence grew rapidly in size and complexity. Mission stations were established in all the new coastal and riverine treaty ports and spread from there into the interior. By 1900 foreign Protestant missionaries and their wives in China totaled about three thousand, representing several denominations and more than sixty agencies from Western countries. Female missionaries (married and single) outnumbered male missionaries and played an active role in the dissemination of the Christian message.

The growth of the missionary enterprise did not go unchallenged. In spite of the continuous expansion of Christianity, its native adherents amounted to only a fraction of 1 percent of the total population of China. However, they were protected by the treaties, backed by foreign diplomatic and sometimes military intervention. Their increasingly powerful social and political role was, however, resented by both rural elites and common people. Moreover, Christian beliefs and practices undermined long-established traditions and provoked the anger of non-Christians. Anti-Christian agitation, fed by inflammatory rumors, created fear and suspicion that resulted in violent incidents. These increasingly endemic local tensions reached a climax in the intensely xenophobic Boxer Uprising of 1900 in which many missionaries and thousands of Chinese Christians were killed.

**Chinese Christianity in War and Revolution**

The aftermath of the disastrous events of 1900 brought about significant changes in China’s relations with the West. Traditional anti-Christian sentiments subsided significantly, and missionaries and Christians were able to play a more constructive role in Chinese society. At the same time Protestant Christianity became much more diverse than it had been before 1900. Many new Christian mission groups established themselves, including Pentecostals and Adventists. Many more independent or “faith” missionaries came to China. Meanwhile, the mainline mission societies and their churches, schools, and hospitals also grew substantially.

In the early twentieth century, against the background of growing Chinese nationalism, the contours of an emerging Chinese Protestant Christianity began to take shape, as indicated by the growth of independent Chinese Protestant forces. The early 1920s brought the formation of an interdenominational Church of Christ in China, a Sino-foreign body with a significant degree
of Chinese leadership and responsibility. The National Christian Council, a Protestant coordinating and liaison body, was also a product of this period. However, these changes did not really constitute a great deal of movement toward an authentically indigenous Chinese church. Attitudes of missionary paternalism remained strong and were exercised primarily through financial control.

Around 1920 a rather more radical independent sector of Chinese Protestantism came into being, including the True Jesus Church, a Pentecostal church founded in 1917; the Assembly Hall (Little Flock), organized in the mid-1920s and led by Ni Tuosheng (Watchman Nee); and the Jesus Family, a unique Pentecostal communitarian church started by Jing Dianying in rural Shandong Province in the 1920s. In addition, several individual evangelists and teachers emerged, including Wang Mingdao, famous for his conservative theological stance and outstanding moral rectitude, and the radical revivalist preacher Song Shangjie (John Sung).

In spite of the growing number of Chinese priests in Catholic missions, the move toward greater leadership roles for them was rather slower than among the Protestant establishments. The Belgian Vincentian missionary Vincent Lebbe pleaded passionately for greater involvement of indigenous clergy in the running of the Catholic enterprise. His concerns are reflected in the apostolic letter Maximum illud issued by Pope Benedict XV in 1919. It deplored, among other things, the effects of European nationalism on the Catholic church in China and called for the elimination of entrenched prejudices of Western
priests as well as eventual ecclesiastical administration by the Chinese clergy. The lack of enthusiasm among the Catholic missionary community notwithstanding, the process gained momentum with the consecration of six Chinese bishops in Rome in 1926.

Although the rising tide of nationalism and revolution fostered the radical anti-Christian movement in urban China in the mid-1920s, the prevailing chaos caused by political instability and military conflicts during the early republican period (1912–1927) created new opportunities for foreign missionaries and Chinese converts. The Christian organizations were able to expand their routine social service operations, especially during the War of Resistance against Japan (1937–1945). Another important development occurred in 1939 when Pope Pius XII reversed the fateful ruling of 1715 and permitted Catholics to participate in ancestor worship. Thus, the way was clear for the emergence of a Chinese Catholic church. In this connection Japan’s attempts to control Chinese Christian establishments and remove all other foreign influences in areas under its occupation forced Chinese Christians to assume greater responsibility for maintaining church life. In many ways this development was another important step toward realization of the “three-self” ideal.

Chinese Church under Communism

Although the Chinese Communists had tolerated Christians and missionaries to some extent during the War of Resistance against Japan, their attitude changed dramatically after 1945. After the Communists had gained control of state power in 1949, anti-Christian campaigns were organized throughout the country. By 1954 the foreign missionaries had been either expelled from the country or imprisoned. However, China’s Christians continued to constitute an ideological and organizational challenge to the Chinese state even after the removal of the foreign missionaries. In response, the new government established the Religious Affairs Office (later Bureau), staffed with religious specialists to oversee and control religious affairs. To this end the government sponsored the Catholic Three Self Movement of 1950–1951 to establish a self-governing, self-supporting, self-propagating church free of all foreign influence. The state obtained its objective with the establishment of the National Patriotic Catholic Association (now known as the “Chinese Catholic Patriotic Association,” CCPA) in 1957 and the consecration of government-sponsored bishops in 1958. Officially the Chinese Catholic Church had severed all links with the Vatican.

Many Chinese Protestants had welcomed the Communist victory and were actively involved in setting up a national church body in 1951, for which the name “Three-Self Patriotic Movement” (TSPM) was adopted in 1954. It was utilized by the state to eliminate foreign influence, unite Protestants in one organization, and promote Communist policies within the church. Many of its leaders had been active in the YMCA and YWCA in the 1930s and 1940s. In spite of the willingness of many liberal Chinese Protestants to cooperate with the Communists, opposition remained strong among the more conservative
elements. Many of the indigenous Protestant groups and charismatic evangelical leaders resisted coerced unification or collaboration with the new state. In response the TSPM organized a series of denunciation campaigns against unaffiliated groups and individuals in the 1950s. Jing Dianying, Wang Mingdao, and Ni Tuosheng were some of the prominent victims.

The period from the mid-1950s to the late 1960s was a time of great suffering for Chinese Christianity as a whole. The nationwide mobilization campaigns such as the Great Leap Forward (1958–1960) and the calamitous Cultural Revolution (1966–1976) in particular adversely affected the Christian churches. These events led many outsiders to assume that the Christian faith was doomed in China. Yet by the late 1970s it became clear that it had survived, essentially in the form of clandestine “underground churches” and family prayer meetings. Since then an explosive growth of Christianity has occurred in many parts of the country, both within officially recognized church organizations and unregistered communities. This so-called Christianity fever has been particularly prevalent in Chinese Protestantism. Exact figures are difficult to establish because many Christians do not wish to register with the government-sponsored TSPM or CCPA. Discounting wildly inflated figures, it may be reasonable to accept the latest estimate of 53 million—mainly unregistered—Christians in China, of which 39 million are Protestants and 14 million are Catholics. Yet when considered against China’s total population of 1.3 billion, it is clear that numerically Christianity has remained a marginal religion, accounting for a little over 4 percent of the total.

At the same time Christianity faces a number of problems in China. The process of improving Sino-Vatican relations has been tortuous and slow and in turn has prevented the unification of the official and underground Catholic churches. The severe shortage of priests has placed great responsibility on the laity. Protestant churches are facing similar problems. The reemergence of denominationalism (this development explains in part the persistence of unregistered “house churches” in China) hinders moves toward greater unity and cooperation. Moreover, rapid Christianization has also encouraged certain sectarian tendencies, such as false teachings, extreme doctrines, and immoral practices. Nevertheless, Chinese Christianity as a whole (Protestants, Catholics, and a small number of adherents of Russian Orthodoxy) may emerge as a major force in world Christianity in the twenty-first century.

Regarded as the ancestor of anthologies in Chinese history, Chuci 楚辞 (Verse of the Chu State) is an important literary work of poems, dialogues, hymns to local deities, proverbs and other allegories written during the Warring States period (475–221 BCE) from the southern state of Chu (in modern Hubei and Hunan provinces).

The earliest known edition of the anthology Chuci, in sixteen juan (installments), was recompiled by Liu Xiang (c. 77–76 BCE) from earlier sources. This edition was subsequently augmented to seventeen juan with commentary by Wang Yi (c. 89–158 CE). The Chuci buzhu (Subcommentary on Chuci) of Hong Xingzu (1019–1155), which incorporates Wang’s commentary, is the most important edition. Most of the Chuci poems were written during the Warring States period (475–221 BCE) and performed, sung, and spoken in the Chu dialect. They record Chu culture and history, and present a distinctive Chu style.

The anthology consists of individual poems and suites. The first and most representative work in the collection is the “Lisao” (“Encountering Sorrow”). This first-person, politically oriented poem in 187 couplets is one of the greatest, and longest, poems in Chinese literature. Thus the Chuci style is often simply named, after this monumental poem, the Sao style. The anthology also includes shorter lyrical and narrative poems, dialogues, and hymns to local deities, most of which have traditionally been interpreted as allegories for the poet’s frustrations.

Qu Yuan (c. 340–278 BCE), once a high official of the state of Chu. Many works in the anthology Chuchi were attributed to him, especially the poem “Encountering Sorrow.” Readers of the anthology sympathized with the political misfortunes of Qu, who was slandered, estranged, and finally exiled.
The attribution of the *Chuci* poems is uncertain. Qu Yuan (c. 343–290 BCE), a high official of Chu who was later slandered, estranged, and finally exiled, was long considered the author of “Lisao” and of most of the *Chuci*. These works, accordingly, were read against the story of his political fortunes. Although this view is not clearly proven by the evidence, it has found sympathy from readers who see in Qu Yuan a patriotic hero, who, thwarted in his efforts to serve his king, ended his life by throwing himself into the Miluo River in northeast part of modern Hunan province.

**Encountering Sorrow**

This brief translation by E. H. Parker of Qu Yuan’s famous *Chuci* poem, *Li Sao* (*Encountering Sorrow*), exemplifies the common literary style.

Seize, thus, the moment whilst life is early,
Whilst Vice is of modern birth,
Before King Time with his ruthless sickle,
Sweeps Virtue from off the Earth.

(*Li Sao*, lines 150–51)

Chinese cinema has evolved for nearly a hundred years—from the earliest silent films to the latest box office blockbusters—with a host of renowned directors, screenwriters, and film stars in genres as diverse as martial arts movies, romance, melodrama, and political propaganda. Chinese cinema can be categorized into six generations, each generation reflecting the technology and culture of its time, the politics of government, and the aesthetics and convictions of the filmmakers.

Cinema in China is visually, sociopolitically, and historically significant. Analyzing the key eras in Chinese film history by generation is not absolute, but doing so does provide a conceptual framework to position the changes and rhythms of the medium and its appeal to audiences worldwide.

First-Generation Cinema, 1896–1929

The first film was screened in China on 11 August 1896 by Spanish businessman Galen Bocca. The initial films screened in China were watched in venues such as teahouses and outdoor tents until the transition to modern air-conditioned theatres in Shanghai by the end of the 1920s. The first film production company in China was called “Yaxiya” (Asia), and it was founded by another foreign businessman, Benjamin Brodsky. Ren Qingtai is known for starting film production in China, making his own films by 1905. The initial films he and others made during this early era were often shot with stationary cameras and frequently portrayed famous film opera stars, such as Tan Xinpei.

In 1918 Commercial Press in Shanghai created its motion picture department, and in 1921 it released Yan Ruisheng (director, Ren Pengnian), a film based on the real-life murder of a prostitute. Like cinema in general, it was extremely popular and was reviewed in the newspapers that by the 1920s were covering film. In 1922 Mingxing (Star) Studio was established by Zhang Shichuan and “the father of Chinese cinema,” Zheng Zhengqiu, who wrote the screenplay for the oldest extant film in China is Laborer’s Love (director, Zhang Shichuan, 1922). In 1923 Mingxing Film Company was purportedly saved from financial ruin by releasing an extremely successful melodramatic film entitled Orphan Rescues Grandfather (director, Zhang Shichuan). Other important genres in the 1920s included martial arts films and historical costume dramas, which Tianyi (First) Film Company, founded by the Shao (Shaw) brothers, was famous for producing.

Historical movements and political trends, such as the Republican rebellion of 1911 and the effects of foreign imperialism, influenced China’s film industry and were often depicted visually. For example, ideas that stemmed from the May Fourth Movement (1915–1923, but named for a demonstration in Tiananmen Square on 4 May 1919) led to the production of political films in contrast to escapist, romantic, and entertaining “Mandarin Duck
and Butterfly School” films. And screenwriters and film critics who were members of the Chinese Communist Party (CCP), founded in Shanghai in 1921, introduced artistic debates that would be discussed in film circles for decades.

**Second-Generation Cinema, 1930–1949**

In 1927 179 Chinese-owned film companies operated in China, most of them in Shanghai, but after consolidation in the 1930s “fewer than a dozen” operated (Zhang 2004, 46). It was a time when large crowds went to art deco theaters with seating capacities of more than one thousand to see the most recent films from home and overseas, mostly from Hollywood. Lianhua (United) Film Company emerged as one of the big three domestic studios in the early 1930s alongside Mingxing and Tianyi. Lianhua produced films starring famous actresses such as Hu Die and Ruan Lingyu, and the studio’s memorable titles included *Wild Flower* (director, Sun Yu, 1930), *Song of the Fisherman* (director, Cai Chusheng, 1934), and *Goddess* (director, Wu Yonggang, 1934).

**Silent to Sound**

Technologically, Chinese film of the early 1930s was in the midst of the expensive transition from silent to sound film. The first sound film released in China was made in Shanghai in 1931. Politically, the Chinese Nationalist Party (Guomindang, GMD) was dealing with the Manchurian

Incident of 18 September 1931 and the Shanghai Incident of 28 January 1932, while it also sought to control cinema in China by banning foreign films that portrayed China or the Chinese people in demeaning ways, martial arts and magic spirit pictures that had been popular in the 1920s, and leftwing films critical of the government. Key leftwing film personnel included Tian Han and Xia Yan. Aesthetically, formal debates included whether or not to produce “soft cinema” (entertainment film) or “hard cinema” (social/critical film).

In 1937, during the first part of the War of Resistance against Japan, Mingxing studio was destroyed, Lianhua closed its doors, and Tianyi moved its operations to Hong Kong. Many directors in Shanghai went to Hong Kong, among them Cai Chusheng and Situ Huimin; others went to the GMD wartime capital of Chongqing to make patriotic films for Zhongdian (Central) Film Studio and Zhongzhì (China) Motion Pictures, while others went to Yan’an to make films for the CCP. Chinese filmmaking in Shanghai from 1937 to 1941 was produced in the International Settlements and French Concession surrounded by Japanese occupation, known as the “orphan island.” A renowned film in that era was Mulan Joins the Army (director, Bu Wancang, 1939) by Xinhua (New China) Studio, established in 1934 by Zhang Shankun. In 1941 the Japanese overtook the foreign concessions, and in 1942 the Japanese started Zhonglian (China United) Film Production Corporation in Shanghai, which produced films alongside its other studio, Studio Manei, in Manchuria.

**Cinema Nationalized**

After the Japanese forces were defeated in 1945, the GMD confiscated Japanese film production centers in China as enemy property, nationalizing cinema in China as never before. Displaced film personnel who returned to
Shanghai either chose to work for the GMD studios or to establish new private studios, such as Wenhua (Culture) Film Company. During the civil war (1945–1949) notable films included Spring River Flows East (directors, Cai Chusheng and Zheng Junli, 1947), the classic Spring in a Small Town (director, Fei Mu, 1948), and Crows and Sparrows (director, Zheng Junli, 1949), which was in production before and after the CCP victory in 1949.

Third-Generation Cinema, 1949–1965

The new government was keen to use the medium of film to further its social project as a didactic medium. Films deemed subversive to the CCP, such as The Life of Wu Xun (director, Sun Yu, 1950), were denounced. The government’s Central Film Bureau consolidated all studios into the state system by 1952 under three studio branches: Northeast Film Studio, Beijing Film Studio, and Shanghai Film Studio. Key veterans active in the 1950s film industry included Sun Yu, Lai Chensheng, Situ Huimin, Shen Fu, Zheng Junli, and Cai Chusheng. Hollywood cinema was prohibited, whereas films from the Soviet Union were welcomed to the screens.

This seventeen-year period was marked by moments of cultural openness and censure at the state’s discretion. For example, in China’s highly politicized culture, the Soviet-inspired “socialist realism” style was imposed on narrative films after 1949 because this film style teleologically (relating to design or purpose, especially in nature) and thematically anticipated the triumph of Communism with characterizations of heroic soldiers, workers, and peasants. Xie Jin was an excellent director of this generation of filmmakers because his work followed the political ebb and flow. During the Hundred Flowers movement of early 1957, when CCP leader Mao Zedong seemed to be asking intellectuals to voice criticism of the present state of affairs in order to shake up the bureaucracy, Xie started working on Woman Basketball Player Number Five, which depicts athletes rather than revolutionaries. After the Anti-Rightist Campaign of 1957, the disastrous Great Leap Forward of 1958 to 1961, and ruptured diplomatic relations with the Soviet Union, the government initiated plans to reinstate the intellectuals in a united front from 1961 to 1963, a time referred to as a “cultural thaw.” This was when Xie Jin directed The Red Detachment of Women (1961) about revolutionaries on Hainan Island. In 1962 Popular Cinema magazine initiated the reader-voted Hundred Flowers Film Awards. Red Detachment and its depiction of the pre-1949 era won the awards for best picture, best director, best actress, and best supporting actor. But in 1964 and 1965 the “cultural thaw” ended. Xie Jin’s classic film

A movie set at a film studio in Beijing. By 1952 the Chinese government’s Central Film Bureau consolidated all studios into a state system under three studio branches: Northeast Film Studio, Beijing Film Studio, and Shanghai Film Studio. Photo by Joan Lebold Cohen.
Two Stage Sisters was made in 1965 but was not exhibited upon completion because the Cultural Revolution was about to begin.

**Fourth-Generation Cinema, 1966–1983**

The Cultural Revolution (1966–1976) brought the film industry in China to a standstill. Political pronouncements that served as harbingers for the upcoming devastation were prevalent as early as 1964. After the Cultural Revolution began, many directors and film personalities were punished, put to work in the countryside, or killed—some of them tragically among the number who were displaced throughout China and Hong Kong during the civil war and then returned to make films under the CCP in 1949. During the Cultural Revolution Mao Zedong’s wife Jiang Qing was the figurehead of the film industry. Her strategy was to produce model stage operas, such as an adaptation of The Red Detachment of Women (1971), which would present simplistic, clear-cut delineations between good (CCP) and evil (bourgeois).

After the Cultural Revolution directors who had been trained in cinema but who did not have the opportunity to make films emerged. These directors are known as the “fourth-generation directors” and included Xie Fei, Zhang Nuanxin, and Zheng Dongtian (Zhang 2004, 231). Xie Jin also made melodramatic films alongside this generation. His films denounced both the Anti-Rightist Campaign and the Cultural Revolution. Fifth-generation film challenged the “Xie Jin model” of filmmaking, but before this mainland development is considered, filmmaking in Hong Kong and Taiwan should be examined.

**Hong Kong Cinema**

Hong Kong cinema began with early screenings of films when the island was a British colony. Among key players in the Hong Kong industry by the 1920s was Li Minwei, a founding member of Minxin (New People) Motion Picture Company in 1922, which eventually merged with other companies to create Lianhua film studio in Shanghai. In 1933 Tianyi produced the first sound film in Cantonese, The Platinum Dragon (director, Tang Xiaodan).

An important studio at the time was Grandview, which was initially established in San Francisco.

**Mandarin Films**

Mandarin-language films became prevalent in Hong Kong during the 1930s. In 1937 Tianyi was renamed “Nanyang” (South Sea) and moved to Hong Kong, as did the famous actress Hu Die and film moguls such as Zhang Shankun, who co-founded Yonghua (Forever China) and Changcheng (Great Wall). When Japan occupied Hong Kong from 1941 to 1945, no films were produced in Hong Kong. After 1945 came an exodus of Mandarin film directors, but some remained in Hong Kong during the civil war, when Da Zhonghua (Great China) studio made thirty-four Mandarin-language films. After 1949 came an influx of right-wing directors who moved to Hong Kong as part of a mass migration, and left-wing directors returned to the mainland. The Shaw brothers remained in Hong Kong, and reclaimed their Nanyang Studio, which in 1957 began using the name “Shaw Brothers.”

In the 1950s film in Hong Kong was immensely popular, marked by the stand-out, pop music-filled Mambo Girl (director, Yi Wen, 1957). In the 1960s the two megastudios of Hong Kong, Shaw Brothers and Cathay’s MP&GI (which closed in 1972), participated in a cut-throat race to be the first to produce captivating, blockbuster-style titles. Director Li Hanxiang’s late 1950s and early 1960s Cantonese opera movies were big screen draws, to be followed in the mid-1960s by martial arts films such as those by King Hu. Although cinema declined in the late 1960s, and left-wing studios such as Changcheng were poorly received because of the Cultural Revolution, stars Josephine Siao and Chan Po-chu still brought ardent fans to the theaters.

**Cantonese Films**

King Hu’s Touch of Zen (1970), Bruce Lee’s worldwide hits with Jiahe (Golden Harvest) Film Company, and The House of Seventy-Two Tenants (director, Chu Yuan, 1973) mark the beginning of 1970s cinema in Hong Kong. In 1971 only one film was made in Cantonese, but Cantonese films came back into popularity by the end of the decade. In 1977 the Hong Kong International Film Festival was established. And in 1978 a new wave of films and directors
(such as Tsui Hark, Ann Hui, Yim Ho, and Allen Fong) who wanted to shift the focus of narratives away from simplistic fantastical plots to relevant social issues emerged. In the 1980s key developments included the films of John Woo, such as *A Better Tomorrow* (1986), and, because the market of mainland China was opened to Hong Kong, a wider audience base and studio co-productions. The second-wave directors of Hong Kong in the 1990s included Wong Kar Wai, Stanley Kwan, Fruit Chan, and Clara Law. Director John Woo, actors Chow Yun-Fat and Jackie Chan, and actress Michelle Yeoh moved to Hollywood in the 1990s. Director Stephen Chow’s films in the early 2000s marked the latest global success of Hong Kong Cinema.

**Taiwan Cinema**

Taiwan cinema began within the Japanese colonial system, which imported films from Japan, China, and Hollywood. Films were also produced in Taiwan by the Japanese and by Taiwanese investors. In addition
to the filmic image, film exhibition included a *benshi*, a person who stood in front of the audience next to the screen and both narrated the film and provided an audience response. The Japanese film centers in Taipei and around the island, including production and distribution networks, were taken over by the Chinese Nationalist Party (Kuomintang, KMT) in 1945 when Taiwan was returned to China. The KMT first set up Taiwan Studio in Taipei, and then the government apparatus brought with it Zhongdian (Central) Film Studio, Zhongzhi (China) Motion Pictures, and Nongjiao (Agricultural Education) Film Company when the government fled to Taiwan in 1949.

State production of film in Mandarin in the 1950s stalled initially, but after a decade of trial and error government film got off the ground. After Gong Hong became manager of the Central Motion Picture Corporation (CMPC) in 1963, he produced a series of “healthy realist” films such as *Oyster Girl* (directors, Li Xing and Li Jia, 1964) and *Beautiful Duckling* (director, Li Xing, 1965) that competed financially in the open market with popular films from Hollywood and Hong Kong. The films also

---

**Beijing Opera actor Tan Xinpei in the first Chinese movie *Dingjunshan* (1905).**
served to extend the international market of Taiwan films to Hong Kong, Singapore, and Malaysia. Meanwhile, Taiwanese-language film was an important part of the Taiwan film market. Film declined in the 1970s but re-emerged with New Taiwan Cinema in the early 1980s with a new cultural impetus and government sponsorship. Famous directors included Edward Yang, Hou Hsiao-hsien, and Wu Nian-zhen. Although not successful at the box office, these directors’ films entered international art-house circuits. New strategies and styles by such directors as Tsai Ming-liang were developed in the late 1990s and early 2000s, and the transplanted Taiwanese director Ang Lee (Li An) found success both at home and abroad with *The Wedding Banquet* (1993) and his hit film *Crouching Tiger, Hidden Dragon* (2000). Both films won Taiwan’s Golden Horse Best Film Awards. Today’s Taiwan film productions are intertwined with those on the mainland.

**Fifth-Generation Cinema, 1984–1993**

While fourth-generation directors in the 1980s continued to make reflective films, such as *Sacrificed Youth* (director, Zhang Nuanxin, 1985), the first graduates from Beijing Film Academy, including Tian Zhuangzhuang and Zhang Junzhao, burst onto the scene in 1984 with Chen Kaige’s *Yellow Earth*, featuring cinematography by Zhang Yimou. The term *fifth-generation cinema* primarily refers to the early films of these graduates, and this cinema was referred to as “new Chinese cinema” in the 1980s to distinguish it from cinema of the socialist period.

The imagery in *Yellow Earth* is predominated by aesthetically innovative landscape shots of the sky and rolling hills in the Shanbei region, which contrasts with representations of revolutionaries typically found in films made in accordance with the Xie Jin model. This film, along with other fifth-generation movies, highlights the landscape, people, culture, and history of China over political concerns and the supremacy of the CCP. In this way the films indirectly challenge the stereotypes of socialist realism and the ideology of the Communist revolution. *Horse Thief*, Tian Zhuangzhuang’s film from 1986, depicts the Tibetan landscape, which is geographically as far removed from political centers as possible. *Red Sorghum* (director, Zhang Yimou, 1987), starring Gong Li and Jiang Wen, the latter a sixth-generation director, was popular overseas, winning a Golden Berlin Bear Award. After this film fifth-generation films won over global art-house audiences with a distinct mixture of Chinese folk culture, repressed sexuality, and dynamic landscapes. Zhang Yimou rode a wave of artistic and commercial success overseas while losing his fan base at home. The legacy of fifth-generation cinema stretches to 1993, when Chen, Zhang, and Tian all made watershed films that portrayed the Cultural Revolution.

**Sixth-Generation Cinema, 1994 to Present**

The so-called sixth generation, also referred to as China’s “urban,” “independent,” or “underground” film, initially emerged as members of a new group of filmmakers in China found themselves unable to acquire funding for their film projects after the government permitted rampant privatization alongside the influx of multinational corporations. These new directors found alternative ways to produce films, either by funding movies themselves or receiving investment from overseas. Their films, often touted as “banned in China” by film festivals outside of China because the films were released before receiving government authorization, are often low in production quality. But this feature is worn by the directors as a badge of honor in their attempts to depict what they perceive as their reality, namely, the false values of their socialist heritage, the demolition of old parts of town to make way for new skyscrapers and factories, government corruption, waves of immigration, and the marginalization of prostitutes, migrant workers, and drug addicts. These raw depictions are in opposition to the heightened characterizations of the fifth-generation films.

Rock music is a central theme in many of these films, such as *Beijing Bastards* (director, Zhang Yuan, 1993), *Dirt* (director, Guan Hu, 1994), and *The Making of Steel* (director, Lu Xuechang, 1996). *In the Heat of the Sun* (director, Jiang Wen, 1994), an adaptation of a satiric Wang Shuo novel, questions the validity of accepted versions of history under Communism in China. In films such as Zhang Yuan’s *East Palace, West Palace* (1996), the first famous film from China depicting homosexuality, the power of the government authority is challenged. These films are
made by directors who see themselves as on the margins of culture themselves, and these directors often cast little-known actors and actresses and present their stories in a docudrama style. Depictions of the underprivileged in the face of globalization can be found in *Beijing Bicycle* (director, Wang Xiaoshuai, 2001), and a documentary style permeates *Suzhou River* (director, Lou Ye, 2003). Director Feng Xiaogang’s New Years pictures such as *Big Shot’s Funeral* (2001) take into account the commodification of Chinese culture in a humorous way, while contemporary films by Jia Zhangke expose financial poverty and ruin in difficult, beautiful films such as *The World* (2004) and *Still Life* (2006). These films enter a market in China that is dealing with copyright issues, rampant piracy, and a state funding system that tends to serve only a handful of directors, including Zhang Yimou.

**Cinema Inside and Outside China**

The images that cinema in China has produced have captivated audiences worldwide for nearly one hundred years, and the films that China has imported have been received with critical acclaim. From current mainstream Chinese directors Chen Kaige and Zhang Yimou, Hong Kong directors John Woo and Wang Kar Wai, and Taiwanese directors Ang Lee and Hou Hsiao-hsien, transnational flows of capital and images remain constant, just as they were when the first film was screened in China in 1896. Chinese cinema has always been truly transnational.

*James WICKS*

**Further Reading**

The civil service examination system, a method of recruiting civil officials based on merit rather than family or political connections, played an especially central role in Chinese social and intellectual life from 650 to 1905. Passing the rigorous exams, which were based on classical literature and philosophy, conferred a highly sought-after status, and a rich literati culture in imperial China ensued.

Civil service examinations connected various aspects of premodern politics, society, economy, and intellectual life in imperial China. Local elites and the imperial court continually influenced the dynastic government to reexamine and adjust the classical curriculum and to entertain new ways to improve the institutional system for selecting civil officials. As a result, civil examinations, as a test of educational merit, also served to tie the dynasty and literati culture together bureaucratically.

Premodern civil service examinations, viewed by some as an obstacle to modern Chinese state-building, did in fact make a positive contribution to China’s emergence in the modern world. A classical education based on nontechnical moral and political theory was as suitable for selection of elites to serve the imperial state at its highest echelons as were humanism and a classical education that served elites in the burgeoning nation-states of early modern Europe. Moreover, classical examinations were an effective cultural, social, political, and educational construction that met the needs of the dynastic bureaucracy while simultaneously supporting late imperial social structure. Elite gentry and merchant status groups were defined in part by examination degree credentials.

Civil service examinations by themselves were not an avenue for considerable social mobility, that is, they were not an opportunity for the vast majority of peasants and artisans to move from the lower classes into elite circles. The archives recording data from the years 1500 to 1900 indicate that peasants, traders, and artisans, who made up 90 percent of the population, were not a significant part of the 2 to 3 million candidates who usually took the local biennial licensing tests. Despite this fact, a social byproduct of the examinations was the limited circulation in the government of lower-level elites from gentry, military, and merchant backgrounds.

One of the unintended consequences of the examinations was the large pool of examination failures who used their linguistic and literary talents in a variety of nonofficial roles: One must look beyond the official meritocracy to see the larger place of the millions of failures in the civil service examinations. One of the unintended consequences of the examinations was the creation of legions of classically literate men who used their linguistic talents for a variety of nonofficial purposes: from physicians to pettyfoggers, from fiction writers to examination essay teachers, and from ritual specialists to lineage agents. Although women were barred from taking the exams, they followed their own educational pursuits if only to compete in ancillary roles, either as girls competing for spouses or as mothers educating their sons.
Pu Songling (1640–1715), a failure many times himself, immortalized the travails of those trapped in the relentless machinery of late imperial civil service examinations in his many stories that parodied the examination system. His most famous portrait sketched “The Seven Likenesses of a Candidate”:

A licentiate taking the provincial examination may be likened to seven things. When entering the examination hall, bare-footed and carrying a basket, he is like a beggar. At roll-call time, being shouted at by officials and abused by their subordinates, he is like a prisoner. When writing in his cell, with his head and feet sticking out of the booth, he is like a cold bee late in autumn. Upon leaving the examination hall, being in a daze and seeing a changed universe, he is like a sick bird out of a cage. When anticipating the results, he is on pins and needles; one moment he fantasizes success and magnificent mansions are instantly built; another moment he fears failure and his body is deduced to a corpse. At this point he is like a chimpanzee in captivity. Finally the messengers come on galloping horses and confirm the absence of his name on the list of successful candidates. His complexion becomes ashen and his body stiffens like a poisoned fly no longer able to move. Disappointed and discouraged, he vilifies the examiners for their blindness and blames the unfairness of the system. Thereupon he collects all his books and papers from his desk and sets them on fire; unsatisfied, he tramples over the ashes; still unsatisfied, he throws the ashes into a filthy gutter. He is determined to abandon the world by going into the mountains, and he is resolved to drive away any person who dares speak to him about examination essays. With the passage of time, his anger subsides and his aspiration rises. Like a turtle dove just hatched, he rebuilds his nest and starts the process once again. (Elman 2000, 361)

This account is, of course, fictional, but its cultural content lays out in full relief the psychological strain that candidates experienced inside and outside the examination compounds.

Women along with Buddhist and Daoist clergy were excluded, so the pool of candidates in late imperial China—as in contemporary education circles worldwide—was exclusive. Because of the requirement to master nonvernacular classical texts, an educational barrier was erected as the hidden curriculum that separated those licensed to take examinations and those who could not because they were classically illiterate. The circulation of partially literate nonelites and lesser lights as writers-for-hire was an unintended byproduct of the civil examination’s educational process and explains the value of examinations for the many and not just the few in premodern China.

When modern reformers summarily decided to eliminate the civil service examinations in 1904 the Qing dynasty (1644–1912) undermined its longstanding partnership with gentry-merchant elites. The dynasty fell before a new schooling system could be put in place empirewide. With hindsight one can see that civil service examinations had served both imperial interests and literati values. Along with the examinations the dragon throne (symbol of dynastic government) and its traditional elites also collapsed in the twentieth-century Chinese revolution.

Examinations as Socio-Cultural “Glue”

In addition to their governmental role, imperial Chinese civil service examinations played a central role in Chinese social and intellectual life from 650 to 1905. Beginning in 1400 imperial examiners were committed to the “Learning of the Way” (neo-Confucianism) as the state orthodoxy in official life and in literati culture. From 650 to 1200 literary talent and classical learning had been tested as important, dual-track educational proficiencies. A unifying philosophical orthodoxy was not widely influential in the examination halls until Chinese literati deemed that they needed to speak with a single cultural voice at a time when the political unity of the empire had been squashed by the Mongol conquest (1240–1368). Han Chinese classical scholars built a new cultural and educational fortress around the bequeathed neo-Confucian teachings of the literati of their beloved but vanquished Southern Song dynasty (1127–1279).

Civil service examinations reflected the larger literati culture because they were already penetrated by imperial interests and local elites who together formed the
classical curriculum. Gentry and merchant status groups were defined in part by their examination credentials. The intersections between elite social life, popular culture, and religion from 1400 to 1900 also reveal the full cultural scope and magnitude of the examination process in the 1,300 counties, 140 prefectures, 17 provinces, as well as in the capital region, where they were administered. These regular testing sites, which in terms of the role of police surveillance in the selection process operated as “cultural prisons,” elicited the voluntary participation of millions of men—women were excluded from participating in this aspect as well—and attracted the attention of elites and commoners at all levels of society.

The demise of civil service examinations yielded consequences that the last rulers of imperial China and reformist gentry generally underestimated. The Manchu court was complicit in its own dismantling after the forces of delegitimation and decanonization were unleashed by reformist Chinese gentry, who prevailed in late-nineteenth-century education circles in the 1890s and convinced the imperial court to eliminate the institution in 1904.

Education reform and the elimination of examinations were tied to newly defined national goals of Western-style change that superseded the conservative goals of reproducing dynastic power, granting elite prestige, and affirming the classical orthodoxy. The ideal of national unity replaced dynastic solidarity as the sprawling, multiethnic Manchu empire became a struggling Chinese republic. It was later refashioned as a multiethnic communist nation.
in 1949. With the Republican Revolution of 1911, the imperial system ended abruptly, but its demise was already assured in 1904 when the Qing state lost control of the education system.

**Power, Politics, and Examinations**

Classical philosophy and imperial politics were dubious partners during the Ming (1368–1644) and Qing dynasties when Song classical interpretations became the orthodox guidelines for the examination system. Ming and Qing appropriations of that orthodoxy as a single-minded and monocular political ideology affected politically and socially how literati learning would be interpreted and used. The mark of the late imperial civil service system was its elaboration of the examination model through the impact of commercialization and demographic growth when the reach of the process expanded from metropolitan and provincial capitals to all thirteen counties. In addition, the upsurge in numbers of candidates was marked by degree inflation at the lower levels. Palace graduate degree-holders dominated most positions of higher office. Officialdom became the prerogative of a slim minority. As the door to official appointment, civil service examinations also conferred social and cultural status on families seeking to become or maintain their status as local elites.

Competitive tensions in the examination market explain the police-like rigor of the civil service examinations as a systematic and stylized educational form of cultural hegemony (influence) that elites and rulers could both support. Imperial power and bureaucratic authority were conveyed through the accredited cultural institutions of the Ministry of Rites, the Hanlin Academy, and civil service examinations. Political legitimation transmitted through education succeeded because enhanced social status and legal privileges were an important byproduct of the examination competition to enter the civil service.

Fixed quotas based on the ratio between successful and failed candidates demonstrated that the state saw educational access to the civil service as a means to regulate the power of elites. Government control of civil and military selection quotas was most keenly felt at the initial licensing stages for the privilege to enter the examination selection process at the county level. In 1600 China had perhaps 500,000 civil licentiates in a population of 150 million, or a ratio of 1 licentiate per 300 persons. By 1850, with a population of 350 million, China had only 800,000 civil and military licentiates, but still only about a half-million were civil, a ratio of 1 per 1,000 persons.

Because of economic advantages in south China (especially the Yangzi [Chang] River delta but including the southeast), candidates from the south performed better on the civil service examinations than candidates from less-prosperous regions in the north, northwest, and southwest. To keep the south’s domination of the examinations within acceptable bounds, Qing education officials maintained the official ratio of 60:40 for allocations of the highest *jinshi* (literati eligible for appointments) degree to candidates from the south versus the north, which was slightly modified to 55:10:35 by allocating 10 percent for the central region.

The overcrowded examination hall became a contested site, where the political interests of the dynasty, the social interests of its elites, and the cultural ideals of classical learning were all compromised. Moreover, examination halls empirewide were supervised by literati officials, who were in charge of the military and police apparatus when so many men were brought together to be tested at a single place. Forms of resistance to imperial prerogative emerged among examiners, and widespread dissatisfaction and corruption among the candidates at times triumphed over the high-minded goals of the classical examinations.

**Literacy and Social Dimensions**

The monopolization of “cultural resources” by local elites depended on their linguistic mastery of nonvernacular classical texts tested by the state. Imperial examinations created a written language barrier that stood between those who were allowed into the empire’s examination compounds and those classical illiterates who were kept out. In a society with no “public” schools, education was monopolized by gentry and merchants who organized into lineages and clans to provide superior classical educations. The Mandarin vernacular and classical literacy played central roles in culturally defining high and low social status in Chinese society. The selection process
permitted some circulation of elites in and out of the total pool, but the educational curriculum and its formidable linguistic requirements effectively eliminated the lower classes from the selection process. In addition, an unstated gender ideology simply assumed that women were ineligible.

Literati regularly turned to religion and the mantic (relating to the faculty of divination) arts to understand and rationalize their chances of success in the competitive local, provincial, and metropolitan examinations. Examination dreams and popular lore spawned a remarkable literature about the temples that candidates visited, the dreams that they or members of their family had, and the magical events in their early lives that were premonitions of later success. Both elites and commoners used fate to describe the forces operating in the examination marketplace. The anxiety produced by examinations was a historical phenomenon that was experienced most personally and deeply by boys and men. They encoded fate using cultural glosses that had unconscious ties to popular religion.

The civil service competition affirmed a classical curriculum that consolidated elite families into a culturally defined status group of degree-holders that shared (1) internalization of a common classical language, (2) memorization of a shared canon of classics, and (3) a literary style of writing known as the “eight-legged essay.” Elite literary culture was in part defined by the civil service examination curriculum, but that curriculum also showed the impact of literati opinions about education. The moral cultivation of the literatus was a perennial concern of the imperial court as it sought to ensure that the officials it chose in the examination market would be loyal to the ruling family. For the literatus it was important that the dynasty conformed to classical ideals that literati themselves had formulated.

The bureaucracy made an enormous financial commitment to staffing and operating the empirewide examination regime. Ironically, the chief consequence was that by 1800 examiners no longer could read each essay carefully. Final rankings, even for the eight-legged essay, appeared haphazard as a result. Although acknowledging the educational impact of the curriculum in force, one should guard against portraying weary examiners with so many papers to read as the dynasty’s “thought police,” operating inside the examination halls trying to impose orthodoxy from above. Overall, however, examiners as an interpretive community did uphold canonical standards. They marked their cognitive world according to the moral attitudes, social dispositions, and political compulsions of their day.

**Fields of Learning**

In the nineteenth century the examination curriculum increasingly conformed to the statecraft and evidential research currents then popular. In the late eighteenth century the Qing dynasty had initiated “ancient learning” curricular reforms to make the examinations more difficult for the increasing numbers of candidates by requiring mastery of not one but all of the Five Classics. In addition, the formalistic requirements of a new poetry question after 1787 gave examiners an additional tool, along with the 8-legged essay “grid,” to grade papers more efficiently. Later rulers failed to recognize that an important aspect of the civil service examinations was the periodic questioning of the system from within that gave it credibility from without.

Literati fields of learning, such as natural studies and history, were also represented in late imperial civil examinations, particularly in the reformist era after 1860. Such inclusion showed the influence of the Qing court and its regional officials, who for political reasons widened the scope of policy questions on examinations in the 1880s and 1890s.

**Delegitimation and Decanonization**

Radical reforms were initiated to meet the challenges of the Taiping Rebellion (1850–1864) and Western imperialism. Even the Taipings instituted their own Christian-based civil service examinations in the 1850s. When the examinations lost their cultural luster and became an object of ridicule even among literati-officials, the system was derided as an “unnatural” educational regime that should be discarded. During the 1890s and 1900s new political, institutional, and cultural forms emerged that challenged the creedal system of the late empire and internationalized its educational institutions.
The emperor, his bureaucracy, and literati cultural forms quickly became symbols of backwardness. Traditional forms of knowledge were uncritically labeled as “superstition,” whereas “modern science” in its European and U.S. forms was championed by new intellectuals as the path to knowledge, enlightenment, and national power. Perhaps the most representative change occurred in the dismantling of the political, social, and cultural functions of the civil service examination regime in 1904–1905. By dismantling imperial institutions such as the civil service examination system so rapidly, the Chinese reformers and early republican revolutionaries underestimated the public reach of historical institutions that had taken two dynasties and five hundred years to build.

When they delegitimated the imperial system within two decades starting in 1890, Han Chinese literati helped to bring down both the Manchu dynasty and the imperial system of governance. Their fall concluded a millennium of elite belief in Song dynasty literati values and five hundred years of an empirewide civil service examination. A social, political, and cultural nexus of classical values, dynastic power, and gentry status unraveled as Manchu rulers meekly gave up one of their major weapons of cultural control that had for centuries induced popular acceptance of the imperial system. The radical reforms establishing new schools initially failed, however, because they could not readily replace the public institutions for mobilizing millions of literati in examination compounds based on a classical education.

Traditionalists who tried to reform classical learning after 1898 paid a form of symbolic compensation to classical thought by unilaterally declaring its moral superiority as a reward for its historical failure. The modern invention of “Confucianism” was completed in the twentieth century despite the decline of classical learning in public schools after 1905. In China and the West “Confucianism” became instead a venue for academic scholarship, when the “modern Chinese intellectual” irrevocably replaced the “late Qing literatus” in the early republic. However, the demise of traditional education and the rise of modern schools in China were more complicated than just the end of imperial examinations and the rise of modern education because the latter would also subordinate examinations to new forms of schooling. The ghost of the civil service examinations lived on in Chinese public school and college entrance examinations, which have now become universal and are no longer unique to imperial China.

The Chinese Civil War was a competition for power between Chiang Kai-shek’s more city-based Nationalist forces and Mao Zedong’s more rural Chinese Communist Party. Both sides sought to control and unify China. While Chiang relied on assistance from the United States, Mao won in the end by enlisting the help of China’s people, particularly the rural populace.

The Chinese Civil War was rooted in the competition for power between the Nationalist Chinese forces of Chiang Kai-shek and Mao Zedong’s Chinese Communist Party. Following the defeat of Japan in 1945, the two factions of China’s military competed for power for another four years in the Chinese People’s War of Liberation. The leaders of these two had been chosen by China’s first twentieth-century Nationalist leader Sun Yat-sen, but they had become adversaries before and during the fight against Japan. Chiang Kai-shek headed the Nationalist Chinese forces (Kuomintang, KMT), while Mao Zedong led the Chinese Communist Party (Zhongguo Gongchandang, CCP).

Background of the Conflict
Sun Yat-sen tried to broaden the base of support for his nationalist movement by incorporating the CCP, which had the support of the Soviet Union. Sun had no intention of compromising his own principles for this support, and his death in 1925 led to a power struggle within the KMT. Because Chiang Kai-shek controlled the military forces, he became its primary leader.

In order to develop the resources necessary to modernize a nationalist China, Sun Yat-sen sent Chiang to Russia in 1923 to observe Soviet methods of discipline and indoctrination; upon Chiang’s return in the summer of 1924, Sun had him establish the Whampoa Military Academy in Guangzhou. Much like the military leaders in the American Civil War who were trained at the U.S. Military Academy at West Point, the leaders of both sides of the Chinese Civil War were trained at the Whampoa Military Academy.

The conflict between the KMT and the CCP began when both sides were attempting to subdue Chinese warlords in northern China (1926–1928) and continued through the Japanese occupation (1932–1945). The need to eliminate the warlords was seen as necessary by both Mao and Chiang, but for different reasons. For Mao, their elimination would end the feudal system in China, helping to prepare the country for socialism and communism. For Chiang, the warlords were a threat to the central government. This fundamental difference in motivation continued throughout the years of fighting against Japanese occupation in China, despite a common enemy.

Mao’s Communist forces mobilized the peasantry in rural China against the Japanese, and at the time of the Japanese surrender in 1945 the CCP had raised an army of nearly a million soldiers. The Soviet Union benefited from the pressure Mao’s forces placed on the Japanese, and the
CCP forces were supplied by the Soviets. The ideological unity of the CCP, plus the experience gained in fighting the Japanese, prepared it for the next struggle, which would be against the KMT. Although Chiang’s forces had been well equipped by the United States, they lacked political unity, effective leadership, and experience.

Opening Stage of the Civil War, 1945

When the Japanese surrendered in August 1945, Mao and Chiang entered the next phase of their competition. At that time Mao’s forces controlled the northern part of China, while the Nationalists held the territory south of the Yellow River. This gave Mao the capacity to move into Manchuria, but Chiang’s KMT had control of the large cities of Nanking 南京 (Nanjing), Shanghai 上海, and Chungking 重庆 (Chongqing).

At the time of Japan’s surrender, roughly two million Japanese soldiers were in China. As members of the Allied forces, Chiang’s Nationalist forces, the Soviets, and the Americans wanted to disarm the Japanese and to evacuate them in accordance with agreements made at the Potsdam Conference. The situation was complicated when Mao’s Red Army refused to follow Chiang’s
order directing the Communists to stay away from the Japanese. The American military commander, General Douglas MacArthur, ordered the Japanese to surrender only to Nationalist forces. The Americans assisted the Nationalists by bringing in U.S. Marines to control Peking (Beijing) and Tsingtao (Qingdao), and eventually 53,000 Marines landed in China to assist with the retreat of Japanese forces and to deny the Communists control of major cities. American aircraft also transported over 100,000 Nationalist soldiers to Shanghai, Peking, and Nanking.

The Soviet Army had moved into Manchuria to deal with the Japanese there, but by late 1945 they had planned to withdraw their forces. Chiang feared that this would leave Manchuria open to capture by Mao’s Red Army, and requested that Soviet forces delay their withdrawal. Even as the Soviets remained, Red Army forces led by Lin Biao 林彪 established a foothold in the rural areas of Manchuria and waited for the Soviets to leave. By mid-December, Nationalist forces began arriving in Manchuria, assisted by American naval and air forces.

Attempts at Reconciliation

The United States sent General George C. Marshall to China with the status of “special envoy” to negotiate a ceasefire between the CCP and KMT and to establish a coalition government. In early 1946 Marshall met with Nationalist general Chang Chun 張群 and Communist representative Zhou Enlai 周恩來 to develop plans for an end to the fighting between Nationalist and Communist forces, to establish plans for shared power between the two sides, and for the eventual demobilization of much of the military. While agreements appeared to be progressing well, neither the Nationalists nor the Communists set aside their plans to eliminate the other. General Marshall left China in mid-March to report his progress to President Truman, and within a month full-scale war had broken out between the Nationalists and Communists in Manchuria.

Even as Marshall attempted to restart negotiations, Nationalist and Communist forces continued to fight through the summer in Manchuria. The situation was complicated by the presence of U.S. Marines and naval forces, who were accused by the Communists of fighting alongside the Nationalists.

With no progress being made through his three-man committee, Marshall proposed a new negotiating team that included two members from each side and was headed by the new American ambassador, Dr. Leighton Stuart. This committee failed to end the fighting, and the continued American support of Nationalist military forces convinced the Communists that the U.S. was not neutral in the conflict.

By 1946 Marshall realized that another element of the continuation of the conflict was the fault of Chiang and the Nationalists, especially the extreme right-wing of the party that was headed by Chiang’s adopted nephews Chen Li-fu and Chen Kuo-fu. This reactionary wing of the Nationalist Party continued to interfere with attempts at reconciliation, and in January 1947 General Marshall was called back to Washington after his mission to facilitate reconciliation failed.

The Military Situation in 1946–1947

By the end of 1946 Communist forces controlled nearly three-fourths of Manchurian territory and half of its population. Lin Biao’s army of about 300,000 was smaller than the Nationalist forces in the region, but more motivated and highly disciplined. Most of the weapons the Communists had were either taken from the Japanese, or captured from Nationalists. The Communists controlled the rural areas, while the Nationalists held the major cities.

The Nationalist forces in northern China were equipped with American weapons and vehicles, as well as some aircraft. However, in general, Nationalist soldiers were less motivated, and their officers were often corrupt. One particular failing on the part of the Nationalists was that when they surrendered, they turned over their weapons to the Communists rather than destroying them.

In January 1947, Lin Biao led an attack on the Manchurian capital of Changchun 长春 with a force of 60,000 soldiers. Communist forces captured the town initially, but were soon forced out by the Nationalists. After retreating, the Red Army forces moved against Changchun again in February, but were forced back across the Sungari River a second time. A third Communist offensive in March was beaten back by the Nationalists, but the Red Army had succeeded in wearing down the Nationalist forces.
The continuing Red Army attacks forced the Nationalists to abandon the Liaotung Peninsula in May. Nationalist efforts consisted largely of attempts to hold the cities of Mukden (Shenyang, 沈阳), Changchun, and Kirin (Jilin, 吉林) and the rail lines connecting them.

From January to March, at the same time the Red Army was weakening the Nationalist forces in Manchuria, the Nationalists moved on the Communist-held city of Yenan (Yan'an, 延安), which was defended by a small number of untrained, poorly equipped, Communist forces. When Nationalist forces finally moved into Yenan in the morning of 19 March 1947, they found that the city was empty. The Communist forces had withdrawn entirely, as was the case with most Nationalist attacks on Communist-held strongholds.

Throughout the Civil War, Chiang's American-trained Nationalist forces expended their efforts on targets which would be found empty. However, in addition to expending resources and time, this placed the Nationalists deep into territory held by the Communists, at risk of becoming encircled by Red Army forces.

Communists in Manchuria in the last half of 1947 also reflected this strategy of encircling the enemy. In September of that year another Communist campaign aimed to isolate Mukden. Because the Communists controlled the countryside and had the support of the rural population, the continued Nationalist control of the cities did not undermine this Communist control. Despite Chiang’s declaration in January 1948 that Communist forces had failed in their efforts to encircle Mukden, the real cost for the Nationalists by this time was the loss of half a million men to combat, desertion, or capture in northeast China.

### Ideological Aspects of the Civil War

Throughout the conflict, the Communists used the traditional resentment of peasant farmers toward landowners to their benefit. The KMT were portrayed to Chinese farmers as landlords and warlords, while the Red Army soldiers were seen as commoners.

During the Civil War, CCP forces were required to be more mobile than they had been during the Japanese conflict, and therefore they could not serve as both farmers and soldiers. To meet the need for village organization, the position of village activist was established to mobilize the masses to support the Communist forces. In 1947 the Land Reform Law authorized the confiscation of land held by the KMT. Also in 1947, as a reflection of this growing power, the Communist forces were renamed the Chinese People’s Liberation Army (Zhōngguó Rénmín Jiefàng Jūn, PLA, 中国人民解放军).

Differences between Communist and Nationalist forces were very clear. Most of the Red Army forces were volunteers from the regions where they fought. Nationalists, on the other hand, had been conscripted into service and were fighting far from their homes, and thus suffered from lack of morale.

Sentiment of the two sides toward the United States was also quite different. Although the Communists were equipped with many American weapons, vehicles, and communication equipment, these had been captured from the Nationalists. The Communists remembered America's support of the Nationalists, the provision of equipment and air transport to Chiang's forces, and General Marshall was portrayed as a conspirator who had supported Nationalist interests rather than as a mediator.

### The Military Situation in 1948

Lin Biao launched another attack on Mukden in January 1948. To emphasize the need to hold this city, Chiang Kai-shek flew to Mukden to direct its defense. Lin was able to stop reinforcement of Mukden by rail, and Chiang was left with only aircraft to resupply Mukden. Lin's Red Army forces gradually took the surrounding cities, essentially leaving Mukden isolated as the only major Nationalist-held region in Manchuria.

American advisors had long advised Chiang to abandon Manchuria to the Communists, but he refused. Although Nationalist forces were better equipped than the Red Army forces opposing them in Manchuria, Chiang's generals seemed only willing to defend their areas of control, and did not attack the Communists.

To the southwest, Communist forces again moved to retake Yenan, which the Nationalists had given up in April. The Nationalists were able to defeat a Communist offensive in Sichuan Province 四川省 that month, but the Communists still controlled the countryside in Shaanxi 陕西省 and most of the Sichuan Province.

By the spring of 1948 the Nationalists had not only suffered the loss of nearly all of Manchuria, but much of
the territory south of the Yellow River that they had held in 1945. Between March and May of 1948 the city of Luoyang 洛阳 was taken by the Communists, retaken by the Nationalists, and finally retaken by the Communists, who took prisoner some 25,000 Nationalists in mid-May.

By the summer of 1948 the greatest part of the fight between Mao’s Communists and Chiang’s Nationalists had shifted from Manchuria to central China. The Red Army had steadily grown in size and armaments since 1945, while Nationalist forces had been reduced by about one-third. The Communists were supported by most of the rural population, while the Nationalists were generally disliked by them.

As the number of cities held by the Nationalists decreased during 1948, Chiang became more determined to hold them, a tactic which had been failing since 1945. Chiang’s American advisors, headed by General Barr of the Joint U.S. Military Advisory Group (JUSMAG), repeatedly encouraged Chiang to give up cities that could not be held and to concentrate on those which could. Chiang put his faith in his air force’s ability to airlift men and equipment where he wanted it. However, one of the last major Nationalist cities, Jinan 济南, fell to the Communists in September when the Communists first seized the city’s airfield, then captured the city and the Nationalist garrison there.

The following month Lin Biao again led the Red Army against Nationalist forces in the last holdout cities in Manchuria, capturing land, weapons, and high-ranking officers. Other than Peking and a few cities in the north, this left Chiang with only Xuzhou 徐州, Nanking, Shanghai, and the southern and western parts of China under his control. Again, the Nationalists sought only to defend their territory instead of attacking the Communists, and entire Nationalist divisions deserted to the Communist side. The battle for Xuzhou lasted more than two months, and the Nationalist army lost more than a half a million men who were killed, captured, or defected.

Political Ramifications of the Nationalist Military Defeat

Chiang Kai-shek’s military and political failures were due at least in part to his unwillingness to accept the advice of his American advisors. General George Marshall had attempted to resolve the conflict between the Nationalists and Communists, but had failed largely because of Chiang’s intransigence. Similarly, Chiang had rejected the advice of General Barr of JUSMAG. Once his forces at Xuzhou had been defeated, he sent his wife, Madame Chiang Kai-shek, to Washington to make an appeal for more assistance. Arriving in early December 1948, she was coldly received and before the month was over American support for Chiang’s government was terminated.

Final Defeat and Departure

One of the last Nationalist generals to maintain a defense against the advancing Communist forces was General Fu Zuoyi 傅作义, who commanded the railroad corridor connecting Peking with the last of the cities held by the Nationalists. In November and December 1948 Lin Biao led attacks against Fu’s forces, and Fu gradually retreated. Rather than engage in a military bombardment of Peking, Fu and Lin agreed to allow the Communist capture of the city. The twenty-five divisions under Fu’s command would eventually be absorbed into the People’s Liberation Army.

Chiang Kai-shek stepped down as leader of the KMT in January 1949 and was replaced by his vice-president, Li Zongren 李宗仁. Li and Mao entered into negotiations for peace, but Nationalist hardliners rejected Mao’s demands. The Communist military capability was a determining factor in resolving the impasse, and when Li sought an additional delay in mid-April 1949, the Red Army crossed the Yangzi (Chang) River. Chiang Kai-shek fled to the island of Formosa (Taiwan, 台湾), where some 300,000 soldiers had already been airlifted. Chiang also relocated his air force in Taiwan and sent the 26 naval vessels of the Nationalist navy there.

The final Communist assault against Nationalist forces began on 20 April 1949 and continued through the summer. By August the Red Army controlled nearly all of mainland China; the Nationalists held only Taiwan and the Pescadores Islands (P’eng-Hu Ch’üan-Tao, 澎湖群島), Guangdong 广东, and a few regions in the far west. From Taiwan, Chiang’s air force attempted to bomb the mainland cities of Nanking and Shanghai, but to no effect. Chiang’s ground forces attempted a return to the mainland, but without any long-term success, and the last of the Nationalist leadership evacuated the city of Chengdu 成都 on 27 December 1949.
This left Mao Zedong’s Communist forces in control of all of China except Hainan Island, Tibet, and Taiwan. The Nationalist forces on Hainan were defeated by Lin Biao’s forces in April 1950, and Lin’s forces moved into Tibet to control that region as well. In just over five years, the Chinese Communists had defeated a military force supplied and trained by the most powerful government in the world. This demonstrated that the effectiveness of the mass movement centered in the rural population used by Mao was more effective than the Nationalist strategy of controlling population centers.

只许州官放火，不许百姓点灯

*Zhī xǔ zhōu guān fāng huǒ, bù xǔ bǎi xìng diǎn dēng*
Through her regency Cixi held power over Qing dynasty political life for almost half a century. She supported officials who encouraged the anti-foreign Boxer movement and accepted the humiliating treaty, the Boxer Protocol.

Wang Yehonala of the Manchu Blue Banner, also known as “Cixi,” held power over Qing dynasty (1644–1912) political life for almost half a century. She was a consort of Emperor Xian Feng (1831–1861, reigned 1850–1861) and bore his successor, Tong Zhi (1856–1875, reigned 1862–1874). After Xian Feng’s death in 1861, Cixi seized power by removing eight conservative regents from the court and setting up her own regent over the boy emperor. In 1875, after Emperor Tong Zhi died with no heir, Cixi named her three-year-old nephew Guang Xu (1871–1908, reigned 1875–1908) to the throne.

In 1898 Cixi resumed the regency as a result of a coup in which she crushed the emperor’s attempt to push through a number of radical proposals designed to modernize the Chinese government. In 1900 Cixi supported officials who encouraged the antiforeign secret-society Boxer movement. A coalition of foreign troops soon captured the capital, and Cixi was forced to flee from Beijing to northwestern China, where she accepted the humiliating treaty, the Boxer Protocol, in 1901. Returning to Beijing in 1902, she finally began to implement a number of the innovations that the reformers had sought in 1898.
The Empress Dowager Cixi. In 1898 Cixi resumed the regency as a result of a coup designed to crush the emperor's radical proposals in the effort to modernize the Chinese government.

including the inception of China's constitutional establishment. Cixi died on 15 November 1908, one day after the emperor's death.

With almost 10 million square kilometers of territory, China has a wide range of climate, largely determined by two weather systems that divide the country east to west. Vegetation adapts to the climate and is one of the richest in the world.

China covers an area of 9.6 million square kilometers and has an immense diversity in climate and vegetation. More than 1.2 million square kilometers are covered by sand and rock-strewn deserts, whereas another 2.1 million square kilometers have a continuous permafrost, with glaciers covering nearly 60,000 square kilometers. Only an estimated 1.7 million square kilometers are arable land.

China may be divided into two halves roughly along the 102° longitude meridian because, generally speaking, two weather systems exist. The comparatively low areas to the east of this meridian are dominated by a temperate, dry or subtropical, humid monsoon climate, whereas the highlands to the west have a significantly drier continental climate. Apart from factors such as latitude and elevation, deviations in temperatures and precipitation within and between regions are influenced by topographical features. Mountain ranges, plateaus, river valleys, and proximity to the ocean all have an impact on local weather conditions.

East of the 102° longitude meridian, the division between the temperate north and the subtropical south approximately follows the Qinling Mountains in southern Shaanxi Province and the Huai River, which traverses southern Henan and central Anhui and Jiangsu provinces. North of this line the January mean temperatures decrease from zero to below −20°C in the northeastern province of Heilongjiang, whereas Hainan Island in the far south enjoys a tropical climate, with annual average temperatures between 22°C and 26°C. The July mean temperature for the same area, with an elevation below 1,000 meters above sea level, shows little difference from north to south. Annual precipitation decreases from more than 2,000 millimeters in the southeastern coastal provinces to 500–750 millimeters in the northeast. The rainy season follows the southeastern summer monsoon, which lasts from April to September in the southeast, whereas it is considerably shorter in the northeast, lasting only through July and August.

Tropical China includes the Leizhou Peninsula of southern Guangdong Province, Hainan Island, parts of Taiwan, and the five thousand islands and islets of the South China Sea, which covers an area of 2.3 million square kilometers south of the Chinese continent. The largest concentrations of islands are the largely uninhabited and disputed Paracel and Spratly islands. The South China Sea has a monsoon climate, with northern winds in winter and southern winds with high precipitation in summer. Annual temperatures average between 22°C and 26°C. Hainan has an annual precipitation of 1,600 millimeters, which increases with the elevation. Except for February and March the islands of the South China Sea and Hainan are repeatedly hit by typhoons that may last for several days. Situated between the East China Sea and the South China Sea, Taiwan is on the border of the...
subtropical and tropical zones. The eastern plains have an annual average temperature of 22° C, which decreases with the elevation in the mountainous areas in the western part of the island. The July mean temperature of the plains is 28° C, whereas peaks above 3,000 meters may be covered in snow during winter. Annual precipitation varies greatly around the island, from 2,000 millimeters in the south to 6,000 millimeters in the northeast, where the city of Jilong records 214 rainy days a year. In the south rain is more frequent during the summer months, when it is often accompanied by devastating typhoons.

**Subtropical Monsoon Climate**

The roughly 25 percent of China situated to the east of the Tibetan Plateau and south of the Qinling range and the Huai River has a subtropical monsoon climate with long, hot summers and short, mild winters. The area may be divided into three regions: the Yunnan-Guizhou Plateau and the Sichuan Basin in the west, the river plains along the Yangzi (Chang) and Zhuijiang (Pearl) rivers, and the mountainous territories of Zhejiang, Fujian, and southern Jiangxi in the east.

The Yunnan-Guizhou Plateau rises from 1,200 meters above sea level in western Guizhou to about 2,000 meters in northern Yunnan. It is a rugged limestone terrain where the subtropical monsoon climate, combined with the high altitude, means pleasantly warm summers, with July average temperatures between 18° C and 28° C in the low-lying parts in the north and 19° C and 22° C in the higher south. Winters are mild, with January mean temperatures between 3° C and 10° C. As a consequence of the great variation in altitude, especially in Yunnan, local climatic conditions may vary considerably. Annual average precipitation in the Guizhou area is 1,200 millimeters, unevenly distributed over valleys and mountain slopes, and hailstorms and droughts are common. Whereas up to 50 percent of the rainfall in Guizhou occurs during the summer months, in Yunnan the rainy season from May to October accounts for 85 percent of the annual average of 1,000 millimeters, and spring droughts are common. The regions bordering on Laos and Myanmar (Burma) have the most rain, with up to 2,000 millimeters annually.

The Sichuan Basin, which occupies the eastern part of Sichuan Province, has an elevation up to 700 meters above sea level and is surrounded by high mountains. The subtropical climate gives mild winters, with January mean temperatures around 6° C, and hot summers, with average July temperatures of 27° C. The average annual precipitation varies from 600 millimeters to 1,200 millimeters and as high as 1,500 millimeters in the Qingyi River valley in the far west of the basin. The rainy season is in late summer and autumn. The plateau of the western half of Sichuan rises to 4,500 meters above sea level, with peaks such as Mount Gongga reaching to 7,556 meters, more than 6,000 meters above the valley of the nearby Dadu River. Here the climate varies greatly between mountains, with cold and dry weather throughout the year and subtropical valleys with warm winters and cool summers.

The plain along the Yangzi River, which includes the southern parts of Hubei, Anhui, and Jiangsu and the northern parts of Hunan and Jiangxi provinces, has a subtropical climate and four seasons with short springs and autumns. Average January temperatures are between 3° C and 9° C, and July temperatures are between 27° C and 30° C. Extreme lows below −18° C have been recorded in Wuhan, which is otherwise known as one of the “four furnaces” (together with Chongqing, Changsha, and Nanjing) because of an average July temperature of more than 37° C. Half of the annual precipitation of 700–2,000 millimeters falls between April and June, often followed by droughts well into September. The subtropical plain drained by the Zhuijiang River and its tributaries, which flows through the Guangxi Zhuang Autonomous Region and Guangdong Province, have annual mean temperatures up to 22° C. Large parts of Guangdong and Guangxi are above 1,000 meters above sea level and therefore cooler. The river plain has a July average temperature of 27–29° C, whereas January mean temperatures range between 6° C and 15° C. Annual precipitation varies from 1,250 millimeters to more than 2,500 millimeters, with 80 percent falling between April and September.

**Well-Defined Seasons**

The hilly terrain of the eastern coastal provinces of Zhejiang and Fujian and southern Jiangxi farther inland has four well-defined seasons and a typical humid subtropical monsoon climate, with average temperatures reaching between 27° C and 30° C in July and between 6° C and 9° C.
in January. Several mountain ranges, of which the highest is the Wuyi on the border between Jiangxi and Fujian, run parallel with the coastline and are traversed by rivers, resulting in many ravines and a highly serrated landscape. Local variations in weather conditions depend on elevation and location on leeward and windward slopes of the ranges. Extreme low temperatures in the mountains go down to −9° C, whereas the coastal valleys record summer temperatures well above 40° C. The annual precipitation varies greatly, from 900 to 1,500 millimeters on the coastal areas of Fujian to 2,200 millimeters in the mountains, with 40–50 percent falling in spring and early summer, followed by frequent typhoons and torrential rain from July to September.

The area north of the Qinling range and the Huai River is in the temperate zone; the low plains and the coastal areas in the east have a monsoon climate with hot, wet summers and cold, dry winters, and to the west the loess (an unstratified, loamy deposit) plateau has a predominantly continental climate. The Gulf of Bohai and the Yellow Sea (Huang Hi) have January mean temperatures that vary from −4° C to 3° C from north to south, and the July mean temperatures are between 26° C and 29° C. In the dry, cold winters Bohai and the inner Yellow Sea freeze over, and ports may be ice-locked for up to eighty days. The annual average precipitation increases from 570 millimeters in the Bohai area up to 1,200 millimeters in the southern parts of the Yellow Sea. In the north up to 75 percent of the annual precipitation falls in July and August, compared to 40–60 percent in the south. The northeastern plain, which incorporates Liaoning and Jilin provinces, has average January temperatures ranging from −5° C near Bohai to −21° C, whereas the coastal valleys record summer temperatures well above 40° C. The annual precipitation varies between 600 millimeters in the lowlands and 1,000 millimeters on windward slopes of the mountains and is largely concentrated in the summer months.

The Huang (Yellow) River plain covers the greater parts of Hebei, Henan, Shandong, Anhui, and Jiangsu provinces. In Hebei the annual mean temperatures increase from 1° C in the mountainous north to 15° C in the south, and the average January temperatures are −21° C and −1° C, respectively, with extreme lows down to −43° C in the north. July mean temperatures range from 18° C in the north to 27° C in southern Hebei, where summer temperatures above 40° C are common. Up to 80 percent of the annual precipitation of 350–750 millimeters falls during the three summer months, with little or no rain on the leeward slopes of the mountains. The remaining part of the Huang River plain has a more uniform climate, with four well-defined seasons. Average winter and summer temperatures vary only slightly, −2° C to 3° C in January and 24° C to 29° C. The northern plain in eastern Henan and Shandong has significant higher differences between absolute high and low temperatures, and torrential rainstorms alternate with periods of drought. The annual precipitation averages 600–900 millimeters.

**Huang River**

The severely eroded loess plateau, which covers southern Gansu, Ningxia, Inner Mongolia, Shaanxi, Shanxi, and the western part of Henan, is drained by the Huang River. Except for the southern tips of Gansu and Shaanxi the plateau has a temperate continental climate, and it is considerably colder in Ningxia and Inner Mongolia in the north, with average January temperatures from −30° C to −10° C, as opposed to −3° C to 3° C in the south. July temperatures average between 15° C and 26° C in the north and 20° C and 28° C in the south, where summer temperatures above 40° C are frequent. The southern plateau receives 500–860 millimeters of rain a year, 60–70 percent of which falls between July and September. The annual precipitation decreases from south to north and east to west to as little as 100–200 millimeters in Inner Mongolia.

The topographical features of western China are arguably the most extreme on the planet, with the world’s highest mountain range and plateaus, deep river canyons, huge deserts, and depressions below sea level next to snow-capped peaks rising to 5,400 meters. The area consists of the autonomous regions of Tibet and Xinjiang Uygur in the southwest and northwest, respectively,
the former covering 1.2 million square kilometers and the latter almost 1.7 million square kilometers. Qinghai Province and the northwestern parts of Gansu add another 1 million square kilometers to this diverse territory, which has a distinct continental climate with marked differences between summer and winter and day and night temperatures. The climate ranges from warm temperate in the comparatively low-lying areas of Xinjiang and Gansu to alpine in the southern Tibetan Plateau, which is situated up to 5,000 meters above sea level. Except for some mountain regions and the valleys in southeastern Tibet, the annual precipitation in the greater part of western China is below 250 millimeters and virtually nonexistent in some parts of the deserts of Xinjiang. In southeast Tibet, which is affected by the southwestern monsoon, up to 90 percent falls in the rainy season between June and September, whereas the annual rainfall in the north is evenly distributed throughout the year.

Xinjiang is divided by the Tianshan range into the large Tarim Basin in the south and the smaller Junggar Basin in the north. The Tarim Basin, which is separated from the Tibetan Plateau in the south by the Kunlun and Altun mountains, is dominated by the Taklimakan Desert. Whereas all of Xinjiang has a warm, temperate continental climate with hot days and cold nights, the temperature differences between north and south are significant. Average January temperatures in the south vary between −8° C and −10° C, as opposed to −15° C and −20° C in the north. Winter temperatures in the northeast may drop below −50° C. July average temperatures in the south are between 25° C and 27° C and only slightly lower in the north. The hottest place in Xinjiang (and China) is the Turpan Depression just south of the Tianshan range, which has an elevation of 154 meters below sea level and summer temperatures recorded as high as 48° C. Except for the Tianshan range, which may have an annual rainfall of 500 millimeters or more, the average in the north is between 150 and 250 millimeters and in the south as little as 50–100 millimeters. The Turpan Depression receives only 4 millimeters a year.

Vegetation

The vegetation adapts to the climatic zones of the different latitude regions as well as the various altitude belts, and in terms of biodiversity (biological diversity in an environment as indicated by numbers of different species of plants and animals) the vegetation of China is one of the richest in the world. In addition to the factors determining weather conditions, vegetation depends on soil types and the extent to which humans have affected it by cultivation, deforestation, mining, and other practices. Little natural plant life has survived undisturbed in the eastern China plains, where cultural vegetation is dominant. In the northern temperate zone crops such as wheat, millet, corn, and soybeans are widespread, whereas rice is the major crop in the subtropical south.

About 12 percent of the total area of China is covered with forests, and about 50 percent of that consists of coniferous forests, which may be found in all climate zones. Cold, temperate or boreal coniferous forests are common in the northeast and on mountain slopes throughout China and include species such as pine, fir, spruce,
and larch. Spruce and fir are especially numerous in the mountainous regions in the southwest, and together with larch they constitute an important source of raw materials for the timber industry. Coniferous forests of warm, temperate zones consist of various types of pine and are mainly found as plantations in northern China and on the lower mountain slopes of northern Sichuan and southern Shaanxi. Subtropical and tropical zones are characterized by a great diversity of local coniferous forests, many of which contain species endemic to China and even species that were believed to be extinct. The Dawn redwood (*Metasequoia glyptostroboides*) was known only from fossils until it was discovered by biologists in the 1940s in Sichuan and Hubei. In addition to pine these forests include fir, cypress, and cedar; for example, the Chinese cedar (*Cryptomeria fortunei*) may reach a height of 73 meters and is among the tallest trees in China.

Broad-leaved forests account for about 47 percent of China’s forested area, whereas only about 3 percent are mixed coniferous and deciduous forests; the latter are mainly limited to a few regions in the northeast and some small forests in subalpine mountain areas of southern China. Deciduous broad-leaved forests are common in mountainous regions in all climate zones, and the most important species are oak, beech, alder, birch, and popular. Many types of oak and birch forests are found, and a larger variety of species, such as aspen, maple, willow, and elm, may be observed in beech forests. In the subtropical zone with high precipitation the evergreen broad-leaved forests, which are characterized by an overwhelming diversity of species, are widespread. Dominant species vary greatly, and in northern areas of the subtropical zone and at altitudes up to 2,000 meters mixed deciduous and evergreen broad-leaved forests are common. Generally speaking, the broad-leaved forests of China are seriously threatened by deforestation, which turns large forest areas into plains or substitutes them with new conifer or bamboo plantations.

Mangrove forests are found along the southern coast and on the island of Hainan, and tropical rain forests stretch roughly from the coasts of Guangdong Province westward until reaching an elevation of about 1,000 meters in southeastern Tibet. Although they are comparatively small, the richness and diversity of species in this area exceeds those of all other regions. In spite of increasing awareness of the need for conservation and the establishment of nature reserves, the areas covered with tropical rain forests are still under pressure from advancing civilization and exploitation by monocultural plantation operations.

The Tibetan Plateau is a treeless wetland and steppe (vast, usually level and treeless tracts in southeastern Europe or Asia), which gradually turn into an alpine desert in the higher and more arid northern part, where elevation is above 5,000 meters. On the southern and eastern edges and in the deep river valleys forests grow in distinct vertical climate belts. Although the greater part of Xinjiang is characterized by sand deserts, salt marshes, and arid grassland, some irrigation-based oasis agriculture produces wheat, corn, and fruit. The forested slopes below the alpine tree line of the Altay and Tianshan mountains are mostly populated with larch, spruce, and fir.

Climate Change—Export Emissions

Qihòu biànhuà—chūkǒu páifǎng
気候変化—出口排放

China currently emits more CO₂ into the world’s atmosphere than any other country (but not more per capita). It faces international pressure to control these emissions because they are a primary cause of climate change, but China claims it should not be held responsible for CO₂ “export emissions” that can be attributed to the production of items for export to the United States and other nations.

It is an accepted fact that China’s exports are responsible for large amounts of greenhouse gas emissions; in 2005, carbon dioxide emissions from China were estimated at 1700 Mt (million metric tons, compared to around 30,000 Mt emitted by humans due to fossil fuels each year), or 6 percent of global emissions from fossil fuels, which is unusually high, as US exports are about 500 Mt. Reacting to international demands to reduce greenhouse gases, China has claimed that limits on carbon dioxide emissions would hamper both economic development and its efforts to relieve poverty. It has also emphasized that per capita emissions ranked only seventy-third in 2004, but this ranking is higher than some developed countries, and it is growing rapidly. China also argues that its historical, cumulative contribution to carbon emissions is low, and while this is true on a per capita basis (China ranked ninety-second in cumulative emissions from 1900 to 2004), it is fourth in cumulative emissions since 1990. A final argument against mandated emissions limits is related to the role of exports (that is, products made in China for sale elsewhere): China claims that it should not be held responsible for emissions that can be attributed to the production of items for export to the United States and other nations.

Gauging the contribution of exports to China’s carbon dioxide emissions is not easy, but they have clearly risen dramatically over the past decade. A 1997 study by the ecologists Ahmad and Wyckoff found that 15 percent of China’s emissions were “embodied” in products to be exported to other countries (that is, they were the byproduct of the manufacturing of toys, electronics, shoes, and other exports, while only 3 percent of China’s domestic emissions were imported. By 2001, further studies found that the figures had increased to 24 percent and 7 percent respectively, showing that a larger volume of goods was being traded. But the export amount is still much higher than that of imports, as one would expect from the current balance of trade between China and, for example, the United States.

Export Growth

In 1987, 12 percent (230 Mt) of China’s domestic carbon dioxide emissions were created during the production of exports; by 2005, this figure steadily had risen to 33 percent (1700 Mt). These numbers closely mirror the rise of exports as a percentage of China’s gross domestic product.
(GDP), which suggests that export products are no more or no less carbon-intensive than products for domestic consumption.

Of China’s 1700 Mt of export emissions in 2005 (which was comparable to the 1850 Mt total emissions of Germany, France, and the United Kingdom), 22 percent came from exports of electronic goods, 13 percent from metal products, 11 percent from textiles, and 10 percent from chemical products. The recent surge in export emissions can be attributed to value-added products, which is evident when compared to previous years. In 1995, for example, the breakdown was very different: 19 percent textiles, 13 percent electronics, 12 percent machinery, 10 percent chemicals, and 7 percent metal products. Emissions embodied in primary product exports—such as minerals, raw timber, raw chemicals, and basic metals—decreased from 20 to 24 percent during the years from 1987 to 1992 to only 13 percent during the years from 2002 to 2005, showing how the Chinese economy has evolved into producing higher value-added items, such as electronics, which are more valuable as a product than their parts combined.

International attention to China’s role in causing—and mitigating—climate change shows how important trade is in the environmental profile of many countries. In general, small countries have larger shares of domestic emissions from the production of exports (for example, most European countries have a 20 to 50 percent share) while relatively self-sufficient countries have lower shares (such as the United States with 8 percent, Japan with 15

Exhaust from a factory near a beach in China. If China doesn’t adopt advanced energy technologies and policies to cut energy-demand growth, the country’s energy consumption and carbon dioxide (CO₂) emissions could grow more than fourfold in the next twenty years. PHOTO BY JOAN LEBOLD COHEN.
percent, India at 13 percent, and South Korea, 28 percent). China does not fit into this categorization because it is a large country with a large share of exports contributing greenhouse gases; its exports therefore play a more important role in its environmental profile.

Environmental Implications

Experts question whether the rapid growth of exports in China (or any other country) comes at the loss of production in developed countries, a phenomenon termed “carbon leakage” or the “pollution haven hypothesis.” The Intergovernmental Panel on Climate Change (IPCC), the international group that represents the consensus on climate change science, has not rated carbon leakage as very important, because its definition of leakage only considers marginal emission changes in nonindustrialized countries that have been caused by climate policy in industrialized countries. It remains unlikely, however, that this is the case in China, where the increase of emissions is most likely a byproduct of China’s other advantages for production—in particular, lower environmental standards and lower labor costs.

A large proportion of goods responsible for China’s export emissions go to the developed world: approximately 27 percent to the United States, 19 percent to the twenty-seven European Union countries, and 14 percent to the other remaining Annex B countries, mainly Japan, Australia, and New Zealand. (Annex B countries are those industrialized nations that have agreed to emissions caps according to the Kyoto Protocol, a binding intergovernmental agreement signed in 1992.) While approximately 40 percent of China’s export emissions go to other developing nations, flows to these countries may displace their own domestic production or production from another trading partner that might have produced goods with less energy intensity than China. (Energy intensity is defined as the energy required per unit of economic output, or energy demand per unit of GDP.) This may be significant because production is more polluting in China than in many other countries due to inefficient systems and a coal-dominated electricity supply. The apparent low cost of Chinese production comes with other consequences: damage to the Chinese environment and increased energy emissions that contribute to the international risk from global warming. Some energy experts point out that if the Chinese could decrease the cost of the production of environmentally friendly items such as energy-efficient lighting or wind turbines, the effect of emissions would be outweighed by the beneficial impacts of their use.

Potential Solutions

A possible approach to solving the problem of a huge amount of export emissions would be to use monetary or tax policies to discourage large-volume export commodities such as electronics, machinery, metal products, and textiles. But these higher value-added products contribute to China’s economic growth more than primary products like natural resources, so in a time of economic challenge, this could lead to a loss in competitiveness and higher costs to consuming countries through inflation. Over the long term, it is in the interest of both the West and China to lower the energy and carbon intensity of its production practices, and to cooperate on low-carbon research and development.

While China benefits from export growth in terms of its GDP and balance of trade, consumers in developed countries also benefit. For this reason, there are efforts to hold consumers in developed countries at least partially accountable for emissions occurring because of the demand for low-priced goods. If consumers were to take some responsibility for China’s export emissions, it is conceivable that China would be more willing to play an active role in post-Kyoto climate commitments. And if China does not want to be held wholly responsible for its export emissions (as it claims), then it must at least be held responsible for what it imports. This could become important in the future, as China shifts to more of a consumption-driven economy.

Although one-third of China’s carbon dioxide emissions result from the production of exports, the remaining two-thirds need to be addressed as well. Inefficient, coal-dominated electricity production is the major cause of China’s carbon dioxide emissions, accounting for 44 percent in 2005. Urgent improvements are needed in this sector. Increasing efficiency in manufacturing as well as domestic and commercial building and in transportation
is essential. Other solutions are expanding renewable energy generation and investing in new technologies such as carbon capture and sequestration (CCS), which seeks to develop ways to capture, purify, and store carbon dioxide instead of releasing it and contributing to climate change. Allowing parties to the Kyoto Protocol to shoulder some of the incremental cost of CCS as part of their commitment to decrease greenhouse gas emissions would be a first step, as this would allow importers of China's carbon-intensive, emissions-producing goods to invest in lowering the carbon intensity of what they buy.

Further Reading

Cooperation between China and the United States, the world’s two largest emitters of carbon dioxide, to limit emissions and pursue alternative energy paths has become a major global political challenge. NGOs, academic organizations, and policy think-tanks are involved in breaking through current barriers to cooperation.

Cooperation between the United States and China to reduce climate change (or global warming) is widely seen as one of the most pressing issues for the worldwide community. China’s energy consumption and carbon dioxide (CO₂) emissions could grow more than fourfold in the next twenty years, thus catching up with and overtaking large industrialized nations (with the exception of the United States and Canada) in per capita emissions. Or, China could implement advanced energy technologies and policies to cut energy-demand growth, in which case its carbon dioxide emissions might only double. The first case would impact the global environment very seriously; the second case is more tolerable. If the latter is accompanied by significant reductions of greenhouse gas emissions in industrialized countries and the aggressive development of low-carbon energy technology, the world could be on the way to cutting emissions significantly by 2050.

Strategic mistrust between China and the United States, however, has interfered with a binding global agreement on energy caps. The Chinese believe that a commitment to reducing carbon dioxide emissions could stifle their development; the U.S. speculates that, because of its large trade deficit with China, any adoption of a carbon dioxide cap without a comparable commitment by China could drive the two nations’ trade balance out of control.

A solution to the problem of greenhouse gas emissions depends critically on both countries. China and the United States account for nearly 40 percent of current global energy-related carbon dioxide emissions; they also have the greatest potential to reduce emissions growth. The participation of both nations is essential in the effort to establish a global regime to contain these emissions.

Background History

Fossil fuels—coal, oil, and natural gas—provide most of the world’s commercial energy. When they are burned, carbon dioxide is released; it and other greenhouse gases keep solar radiation (or heat) trapped on Earth. This is known as the “greenhouse effect.” According to the United Nations Intergovernmental Panel on Climate Change, the mean global temperature increased approximately 0.6°C from 1890 to 1990, and they predict a 1.1°C–6.4°C rise during the twenty-first century. This increase in surface temperatures on Earth can have catastrophic results, affecting weather, global water levels, and plant and animal life, among other issues. Energy-related carbon dioxide emissions make up approximately 80 percent of the greenhouse gases in the atmosphere, so their containment is a global issue.
While there is disagreement about solutions to climate change, there are some facts that are generally accepted regarding the historical, current, and anticipated future situation of China and the United States and greenhouse gas emissions.

The first mutually accepted fact is that the United States is responsible for 28 percent of total cumulative emissions of carbon dioxide from energy consumption, while China is responsible for 8.5 percent. Because of carbon dioxide's long “residence time” in the atmosphere (more than 100 years), the contributions from many years ago affect the global greenhouse as much as today's emissions. Therefore, the most important measure of energy-use contributions to greenhouse gases in the atmosphere is the cumulative emissions of carbon dioxide.

A country’s energy use conventionally is presented in terms of per capita emissions, in the same way that gross domestic product (GDP) per capita, not GDP alone, is a measure of the economic well-being of a country. (GDP is the total market value of all of a country’s goods and services produced in a given year minus the net income earned abroad.)

In describing contributions of a country, it is useful to present this in terms of per capita emissions, in the same way that GDP/capita, not GDP, is a measure of the economic well-being of a country. That is, over the entire period during which we can estimate carbon emissions due to human activity (roughly since 1850), China’s cumulative per capita emissions of energy-related CO2 are less than 8 percent of those of the United States.

This is generally seen as a remarkable achievement, as virtually all countries undergoing very rapid economic development—China had 9–10 percent annual GDP growth over those two decades—experience energy growth that is faster than GDP growth. China’s reduction in energy demand growth was the consequence of explicit policies carried out domestically. If energy had grown just at the rate of GDP, China’s emissions of CO2 would be more than twice as great as today’s emissions.

Notwithstanding these reductions in growth of CO2 emissions, U.S. CO2 emissions per capita are still greater than those of the European Union countries and 2.1 times those of Japan. The European Union and Japan are not far behind the United States in GDP/capita. But these nations have much less land per capita and have much higher population densities. High population density reduces travel demand and results in smaller per capita emissions.

For industrialized countries, emissions are likely to decline over time in proportion to GDP growth because many activities and products have saturated their markets: For example, not many people are purchasing their first car, and virtually all homes have refrigerators and most are not seeking to have a second. This is confirmed by the fact that from 1975 to the present, the United States reduced the growth of its energy-related carbon dioxide emissions more than any other large industrialized country in the world. GDP per capita grew almost 200 percent while energy consumption (and carbon dioxide emissions) per capita remained constant. But it is useful to use a baseline that has carbon dioxide emissions growing at the rate of growth of GDP when making comparisons among countries.

China and the United States currently produce approximately equal levels of energy-related carbon dioxide emissions and together are responsible for almost half of such emissions worldwide. According to the International Energy Agency’s 2008 World Energy Outlook, China is projected to account for more than 40 percent of new energy-related carbon dioxide emissions globally between 2008 and 2030, thus being by far the largest future contributor to increased concentrations of carbon dioxide in the atmosphere. But in 2006, China instituted a national program to reduce energy intensity 20 percent by 2010; it is noteworthy that in 2006 the energy intensity (energy demand per unit of GDP) decreased by 1.3 percent (that is, energy grew 1.3 percent less rapidly than GDP) and by 3.7 percent in 2007, with greater intensity declines projected for 2008. The program started slowly but is now approaching its annual target.

The United States, meanwhile, has the greatest potential of any country in the world to reduce energy-related greenhouse gas emissions. This is true for two reasons: First, because the U.S. per capita intensity of these emissions is considerably higher than those of other large industrial countries (2.5 times that of the European Union and 2.1 times that of Japan), there is greater opportunity to decrease the numbers; and second, the United States has the scientific, technical, and economic capability of developing viable alternatives to fossil-energy technologies and is likely to be the world leader in any breakthrough technology, if one is developed. Annual growth of energy-
related carbon dioxide emissions in the United States in the coming decades is expected to be in the range of 0.5–1.0 percent unless new policies are enacted to cut carbon dioxide emissions.

For the future, neither China nor the United States have agreed to binding commitments on greenhouse gas emissions. In 1992 the U.N. Framework Convention on Climate Change (UNFCC) established an intergovernmental plan to reduce and mitigate greenhouse gas emissions; the resulting agreement is named the Kyoto Protocol. China is a signatory to the Kyoto Protocol, but it actually contains no binding commitment for developing countries. Recognizing that developed countries are principally responsible for the current high levels of atmospheric greenhouse gas emissions as a result of more than 150 years of industrial activity, the Protocol places a heavier burden on industrialized nations. As of 2008, the United States had not ratified the Kyoto Protocol.

In describing contributions of a country, it is useful to present this in terms of per capita emissions, in the same way that GDP/capita, not GDP, is a measure of the economic well-being of a country. That is, over the entire period during which we can estimate carbon emissions due to human activity (roughly since 1850), China’s cumulative per capita emissions of energy-related CO₂ are less than 8 percent of those of the United States.

This is generally seen as a remarkable achievement, as virtually all countries undergoing very rapid economic development—China had 9–10 percent annual GDP growth over those two decades—experience energy growth that is faster than GDP growth. China’s reduction in energy demand growth was the consequence of

explicit policies carried out in China. If energy had grown just at the rate of GDP, China’s emissions of CO₂ would be more than twice as great as today’s emissions.

Notwithstanding these reductions in growth of CO₂ emissions, U.S. CO₂ emissions per capita are 2.5 times greater than those of the European Union countries and 2.1 times those of Japan. The European Union and Japan are not far behind the United States in GDP/capita. However, these nations have much less land per capita and have much higher population densities. High population density reduces travel demand and results in smaller per capita emissions.

**Two Viewpoints**

It is generally not understood in the West that China has put tremendous effort into reducing the growth of energy-related carbon dioxide emissions through the design and implementation of aggressive and innovative energy efficiency policies. Instead, there is a perception that China has paid little attention to the matter of greenhouse gas emissions. From 2001 to 2006, China’s energy demand and energy-related carbon dioxide emissions grew faster than the 10 percent annual growth of GDP. This led to an increase in China’s emissions from 12.7 percent of global emissions (2001) to 18.4 percent (2006). Many in the United States look at these facts, noting how rapidly China has grown in the past five years, and are aware of the forecasts that predict that a large proportion of the world’s expected increase in energy-related carbon dioxide emissions this century will come from China. Many Americans express concern that emissions reductions applied to the United States could increase the cost of producing goods and services there, thus placing the U.S. at a competitive disadvantage with any country that does not do the same.

But the perspective from China is very different. The Chinese note that per capita energy consumption and carbon dioxide emissions are much lower in China than in the United States. They emphasize the disproportionate cumulative contribution of the United States to the global greenhouse gas problem, pointing out that the United States, with a population one-quarter the size of China’s, is responsible for putting far more carbon dioxide into the atmosphere than has China. This point is made to indicate the inequity inherent in focusing on current emissions while a large part of the problem is caused by emissions over long periods of time.

These views may provide a philosophical underpinning that supports China’s major concern looking forward: China believes that it will need more energy for development—much more. Chinese officials observe that the industrialized countries have already been through the energy-intensive phase of their development, but China is in the midst of its own. The possibility of gaining a competitive trade advantage through a new climate treaty is much less significant to the Chinese than the possible roadblocks to achieving social development goals that could result from a commitment to mandatory emissions targets.

**Efforts Towards Cooperation**

It is not enough that China and the United States both take steps to reduce carbon dioxide emissions; it is essential that the two countries do this cooperatively. As long as China does little to reduce growth of greenhouse gas emissions (or appears to be doing little), it will be politically difficult for the United States to sign a binding international treaty that commits to a serious cap on emissions. And as long as the United States either does little or appears to be doing little, it is impossible to imagine China committing to any international treaty that limits its own emissions.

At a 2008 hearing held by the U.S.-China Economic and Security Review Commission, representatives from the China Energy Group proposed that the United States and China should engage in regular, formal discussions that focus on working together to reduce greenhouse gas emissions, with the goal of influencing global negotiations. A serious proposal agreed to by both the United States and China is likely to be acceptable to both industrialized and developing countries.

A research group that has worked with energy policymakers in China for two decades to analyze, develop, and enhance Chinese energy policy, the China Energy Group further recommended that in the short term, the greatest support the United States can provide to China (and other developing countries) is to build capacity in those countries to create and implement policies and programs
that reduce greenhouse gas emissions. Western resources can provide training and technical assistance to Chinese enterprises that will in turn establish new energy standards and compliance regulations. The assistance develops the potential for the Chinese to pursue energy efficiency, but does not pay for it. Such a program also will need to engage the full participation of the international community: It should include all industrialized countries as donors and key developing countries as recipients. This is not an investment program; it is focused on building capabilities to design and implement policies, many of which will facilitate investments with funds coming from other sources.

In the long term, the solution to climate change will have to rely on technology that is not yet commercialized. New low-carbon technologies are essential to reduce energy-related carbon dioxide emissions to appropriate levels. For the most part, such technology is not available today, and the intellectual property for these technologies does not exist yet. There is a need for programs to support joint development of such technologies, using the technical and financial resources of many countries. The United States government could play a key role in establishing a basis for performing research and development on these technologies with other nations (including China) and the sharing of intellectual property of these future technologies among nations of the world.

The China Energy Group also proposed that the leaders of the high-level teams from both countries should be policy makers above the level of the climate-change negotiators. These discussions should not be construed as bilateral negotiating sessions; the goal is for China and the United States to reach a consensus that can serve as a model for the European Union and developing nations. Any agreement must include binding commitments that will not threaten China’s growth and internal development goals, and that will give China access to the knowledge, tools, and technology that lower the cost of reducing emissions; for the United States, it is crucial that implementation of the agreement will not exacerbate the U.S. trade deficit with China. A formula that might work in China is a commitment that industrial emissions would grow slower than the industrial value added over the next decade, for example, 80 percent as fast, after which time a new formula could be agreed upon. The advantage of this approach is that it places no constraint on the consumer economy, which China views as necessary to meet its social and economic development objectives. A further advantage is that this approach addresses the industrial sector, which is responsible for 70 percent of all energy-related emissions; it thus speaks to the activities in China that are by far the largest contributor to greenhouse gas emissions.

There are other formulas that could be used for China as well. Most involve the adoption of an emissions target that increases as GDP increases, thus assuring China that growth would not be impacted as long as proper measures are taken to reduce the growth of greenhouse gases. Like the industrial emissions approach, the formula could involve a commitment that greenhouse gas emissions grow at a rate lower than that of GDP with the provision of technical support, capacity building, and/or funds to facilitate reductions in greenhouse gas emissions. Achieving better results could trigger greater levels of assistance.

**Trade Policies**

Trade remains a major divisive topic, but there are different ways to deal with this issue. One, for example, is based on the concept of “carbon credits,” a tool formalized in the Kyoto Protocol and monitored by the UNFCC that expects to reduce greenhouse gases by having countries honor their emissions quotas and offers monetary incentives for being below those targets. (This system has been adopted by the European Union, and it has resulted in carbon credits of about $20 or $30 per metric ton.) To avoid impact on trade in the case where limits on Chinese emissions in early years would produce only small increases in the price of its products for export, China would agree to a tax on exports equal to the cost of a carbon credit (in dollars per metric ton). To avoid this being too cumbersome, it would apply only to products that are energy- (and therefore carbon-) intensive in their manufacture. Under this proposal, China would collect the tax and be required to apply it to its program of reducing carbon dioxide emissions. A program such as this would eliminate the trade advantage that China might gain by having less rigid commitments than industrial countries. It would have the further benefit of assuring...
that resources in China would be used to address greenhouse gas emissions.

An international commission would be needed to oversee the uses of the tax in China (and presumably other developing countries, if the approach is extended to them) as well as the provision of resources from the United States and other industrialized countries to support greenhouse gas abatement in developing countries.

**Protecting Economic Growth**

In the United States, economic growth and energy use over a period of a decade or longer are relatively predictable. Absent a multiyear recession, annual economic growth over a period of a decade or more is likely to be 1.5–3 percent. Growth in annual energy demand and energy-related carbon dioxide emissions, without new policies, is likely to be in the range of 0.5–1.0 percent. (With a long-term recession, the growth of energy demand and carbon dioxide emissions will be at a decreased rate, thus lowering the difference between targets and emissions in a base case.)

Forecasts in this range apply to most industrialized countries, for which many consumer products such as refrigerators and cars have already approached saturation. In short, it is possible to understand at a general level what is entailed in achieving certain targets for greenhouse gas emissions over a period of one to two decades.

But for a rapidly developing country such as China, growth in energy demand and resulting carbon dioxide emissions can have much greater variations. The Chinese economy grew at annual rate of 9–10 percent from 1980 to 2000; during this period energy demand grew at an annual rate of 4–5 percent. (In only one year during this period did the increase in energy demand growth exceed even 60 percent of that of GDP.) But from 2001 to 2006 GDP in China continued its growth at 10 percent per year (or greater). One might have predicted that energy demand in China would have grown at a rate lower than 5 percent per year, as it had done over the previous twenty years; indeed, forecasters did predict this. But energy demand grew even faster than GDP during the period, averaging almost 12 percent per year.

Consequently, it is extremely difficult in China, in its present stage of economic development, to predict with any accuracy the energy-demand growth over a ten- to twenty-year period. This is one reason that China cannot accept a binding cap that is expressed in absolute terms, unless such a cap were well in excess of the higher range of expected emissions. (But if a cap were set so high, it would be meaningless.)

China and other developing countries will have the largest emissions in the future, and there is great concern worldwide that China will continue increasing its energy demand and spewing carbon dioxide into the environment forever, or at least for a very long time. But China is in the middle stage of building its infrastructure—housing, commercial buildings, roads, hospitals, schools, and the like. It is at a relatively early stage of increasing the mobility of its population, and large quantities of energy are required to accomplish these tasks. This period is likely to last for fifteen to twenty-five years, depending on whether China continues its breakneck speed of construction and whether large numbers of rural dwellers continue migrating into urban areas. At the end of this construction period, China's economy will be much like today's developed countries. Energy-demand growth will decline markedly, just as it now has in the industrialized world. Scarcity of traditional energy sources could slow energy-demand growth even further in this time.

**Outlook for the Twenty-First Century**

The key question about the future concerns what China's energy demand will be when its economy becomes mature, or when infrastructure is built out and most amenities have been met. If China has a structure of consumption similar to that of the United States today, and the construction techniques and industrial processes are inefficient in their use of energy and other resources, then not only China but the world will be in serious trouble. But from 1980 to 2000, China has shown its willingness to grow its economy while constraining energy growth to less than half that of economic growth. Today China exhibits a serious willingness to once again limit energy growth, and significant support from industrialized countries can help greatly in achieving this objective. If at the
same time the industrialized countries learn to reduce greenhouse gas emissions—and transfer this knowledge to China and other developing countries—then a sincere start at addressing the serious challenge of climate change will be possible. This approach can buy time while energy supply technologies that produce low carbon emissions are developed and deployed on a large scale.

Cloisonné ▶
Cloisonné, also known as inlaid enamel, is a decorative art form brought to China from the West around the fourteenth century. Pulverized enamel or glass is fused onto a metal surface; soldered wires separate the different colors or elements of the design to become part of the design itself. The technique reached its height during the early Ming dynasty.

Cloisonné is a technique employed in the decorative arts in which pulverized multicolored enamel or glass is fused onto a metal surface; the enamel is held in wire cells (from the French cloisons). The technique came to China from the West during the fourteenth century (or earlier) and reached its pinnacle during the early Ming dynasty (1368–1644) under the rule of the Jingtai emperor (1428–1457). In fact, one of the terms by which cloisonné is known in China is jingtai lan. Other terms for cloisonné tell of the technique’s foreign origins: A text from the Ming dynasty states that cloisonné came to China from Da Shi (Arabia) and Folang (Byzantium), thus yielding the terms dashi yao, Arabian ware, and falan or falang, likely a corruption of the Chinese term for Byzantium.

Cloisonné enameling uses cells formed from slender metal wires to hold the enamel paste in place. These wires become part of the overall design of the piece and are soldered onto a metal foundation. After the enamel paste is added to the cells the piece is fired at a temperature high enough to fuse the paste without destroying the metal cells or the metal foundation. Pieces often need to be fired a second time to correct any flaws in the enamel and to fill up the cells. The piece is then polished with a pumice stone to smooth the surface and heighten its luster.

The earliest cloisonné pieces carrying a reign mark date from the reign of the Xuande emperor (1399–1435). The usual colors of these early pieces are a distinctive turquoise blue, deep brown-red, lapis lazuli blue, yellow, green, black, and white. (A true pink was not seen until the famille rose palette was developed for porcelains in...
the early eighteenth century. The pieces are strikingly simple in both decoration and shape. One characteristic of Ming cloisonné is the presence in the enamels of the solder used to hold the metal wires to the base. This flaw was remedied during the late seventeenth or early eighteenth century by the use of vegetable glues, which burned away in the heat of the firing.

During the Qing dynasty (1644–1912) production of cloisonné wares increased because of the establishment of imperial palace workshops under the Kangxi emperor (1654–1722) in 1680. The aesthetic quality of pieces during this time is said to have suffered in the quest for technical perfection. This was especially true during the reign of the Qianlong emperor (1711–1799), when the wires were gilded, frequent firings dulled the finish, and designs were busy and complex.

Today cloisonné continues to be produced using the same methods as in the past, with most of the work being done by hand. But despite the technical achievements of the past several centuries, fifteenth-century pieces remain the apex of the art.

From the prehistoric to the People’s Republic, traditional clothing in China has reflected the culture and the technology of its time. Clothing has been worn to denote rank, to symbolize virtues, and to express political ideology.

Prehistoric Chinese made clothing from animal skins and furs and from plant fibers of hemp, wisteria, and ramie (an Asian perennial plant of the nettle family). Bone, shell, and stone ornaments have been discovered in caves and ancient tombs. Bone needles and awls also have been discovered; the discovery of awls suggests the use of leather for clothing.

Clothes before Qing Rule

By the Shang dynasty (1766–1045 BCE) trade and tribute with neighboring regions were well established. Tribute goods included woven and dyed cloth. Sericulture (production of raw silk by raising silkworms) had grown into an industry, and Chinese silk fabrics were highly prized trade goods. Simple cut-and-sewn garments such as straight, narrow robes, skirts, and trousers were worn during this time. Robes closed to the right, and sleeves were long and covered the hands to show respect. Hair was braided; hairpins were symbols of rank and distinction. Clothing was used to distinguish between stratified social classes.

Clothing continued to help maintain a stratified class system during the Zhou dynasty (1045–256 BCE). The *Zhou li* (Book of the Rites of Zhou) included sumptuary laws (relating to personal expenditures and especially to prevent extravagance and luxury) regulating the use of dress to show rank; the designation of special robes with special symbols worn by the emperor; and the dictate that all garments must close to the right. The usual clothing worn was the long, slim, narrow-sleeved embroidered robe and trousers or skirt; by the end of the Zhou dynasty a spiral-wrapped, one-piece robe was popular. Hats and shoes were symbols of distinction and rank. As Daoism was incorporated into Chinese life, the symbols for the Daoist immortals were frequently embroidered on clothing. These symbols included the fan (life infused into the dead), the bamboo tube (longevity), the magic saber (magic), the pair of castanets (music), the magic gourd (medicine), the flute (harmony), the basket of flowers (longevity), and the lotus flower (purity).

Another philosophical ideology was formed by the philosopher Confucius (551–479 BCE). His teachings included the importance of maintaining an orderly society and filial piety, which became important in some clothing traditions. Correct appearance was believed to help maintain order and to help people recognize and understand authority through clothing, fabrics, and accessories. Filial piety and respect were also expressed through appearance; men and women did not cut their hair because hair, like life, was a gift from one’s parents.

During the Warring States period (475–221 BCE) minority clothing influenced Chinese dress. The *hu fu*, a short jacket and long trousers, was introduced. The *hu fu* was widely adopted throughout China by men and
women, particularly those living in rural areas. Robe sleeves began widening near the end of this period.

During the Qin (221–206 BCE) and Han dynasties (206 BCE–220 CE) color symbolism was defined and became an important characteristic of ceremonial and ritual robes. Black denoted darkness, dawn, or evening; green or blue was considered the color of creation or life; red meant burning brightly and was the color of the sun and happiness; white was associated with opening, clearing, and cracked ice; and yellow denoted sparkling light and sunshine. These colors also symbolized the universe and the elements: Black signified north and water; green or blue signified east and wood; red signified south and fire; white signified west and metal; yellow signified center and earth. From the classical text *Yijing* red became associated with the masculine concept (yang), and blue became associated with the feminine concept (yin). One-piece robes were popular, as was a spiral-wrapped robe;
both had large curved sleeves. Wealth was displayed by type and amount of embellishment and amount of fabric used in the robe. Hats and ribbons continued to denote rank. During the Han dynasty the trade route now known as the Silk Roads was established, and silk was introduced to Europe.

Buddhism reached China by the end of the Han dynasty, and Buddhist symbols were used as embroidery motifs on clothing; these symbols included the parasol (charity), fish (tenacity), the sacred vase (ceremonial), the lotus (purity and marriage), the seashell (appeal to wisdom), the canopy (spiritual authority), and the Wheel of the Law (infinite changing). Toward the end of the Han dynasty women began to favor a two-piece ensemble consisting of a long, pleated, wrap-around skirt and short jacket.

Sui dynasty (581–618 CE) clothing featured a narrow silhouette. Women continued to wear the jacket and skirt; red became the most popular color for skirts. Sleeves could be narrow or wide. A popular robe was the band robe. This robe featured a rounded neckline and a section of fabric sewn to the lower half of the front and back of the robe in a wide, horizontal band. Colors and fabrics continued to be used to indicate rank.

During the Tang dynasty (618–907 CE) Chinese envoys spread Chinese costumes throughout Asia, particularly affecting court dress in Japan and Korea. Tang dynasty dress was more elaborate and had a larger silhouette than the dress of previous eras. High-ranking men wore a stiff leather hoop belt with decorative plaques, often of gold, jade, or silver.

During the Song dynasty (960–1279) cotton was introduced from India and became an important textile crop in China for domestic use and foreign export. It began to replace indigenous cellulose fibers used in Chinese clothing. In particular, cotton became widely used in the clothing of the lower classes. Song dress included large, full robes with large, wide sleeves. Robes opened down center front or closed to the right. Hoop belts with decorated plaques were also worn.

The tradition of foot binding, which was practiced in China before the Tang dynasty, was well established by the Song dynasty. Foot binding was usually characteristic of Han (the dominant Chinese ethnic group as opposed to ethnic minorities) women only. Tiny embroidered shoes, called “lotus slippers” or “lily slippers” became important dress and cultural attire.

Under the Mongolian Yuan dynasty (1279–1368) trade with other countries was encouraged. The cotton industries were well established. The Mongolians considered the Han Chinese inferior but borrowed many Han Chinese dress traditions, such as color symbolism and clothing items denoting rank. The Mongolians reduced the width of the robe and the sleeves and introduced the finial, an ornament worn on the top of hats, to designate rank.

The Ming dynasty (1368–1644) was the last Han Chinese dynasty to rule China. Ming means “brilliant” or “glorious,” and red was its dynastic color. Sumptuary laws from the Han, Tang, and Song dynasties were reestablished, and clothing regulations for all social classes were strictly codified in such documents as the Ming Hui Dian. For the upper classes Ming dress was characterized by extreme width and long, wide sleeves. During the Ming dynasty rank or insignia badges, usually in the shape of a square, were used to indicate the civil or military rank of officials. Civil officials used birds to indicate rank; military officials used other animals to designate rank. These became known as “mandarin badges”; the word mandarin was derived from a 1589 Portuguese word meaning “a Chinese official.”

**Clothes after Qing Rule**

China’s final dynasty was founded by a group of conquering horsemen from the north, the Manchus. The Manchus took the Chinese name Qing, which means “pure” or “clear.” The Qing dynasty (1644–1912) instituted new sumptuary laws, many designed to assimilate the Han Chinese into Manchu culture. All Han Chinese men were forced shave their forehead and to wear their hair in a long queue or braid in the Manchu style (the Queue Order of 1646); those in government positions had to wear Manchu-style garments, namely, the chang pao, a one-piece robe with no pleats and with sleeves ending in the distinctive horse-hoof cuffs. Horse-hoof cuffs were distinctive features of Manchu robes, deriving their name from their resemblance to the hoof of a horse. The wide, flaring cuffs could be turned down to extend over the
hands of the wearer for protection or warmth or to show respect when saluting high-ranking officials.

The Qing dynasty was also responsible for the many regulations that controlled the use and the possession of the dragon robe as a court and official costume. Robes with dragons as the main design appear to have been in existence since at least the Tang dynasty and were worn by imperial and high-ranking officials of each successive dynasty; records also indicate that robes with dragon motifs were given as gifts to foreign heads of state. However, not until the Qing dynasty did the dragon robe become part of the Chinese official costume; in 1759 an imperial edict codified the use of dragon robes according to rank.

The style characteristics of dragon robes worn by the emperor were regulated to set him apart from any other official. Qing imperial dragon robes had nine dragons embroidered on them; only the emperor could have five-clawed long dragons. The emperor was the only person who could have all Twelve Auspicious symbols on his robe. These symbols, whose use dates back to the Han dynasty, represented the qualities desirable in an emperor: enlightenment represented by the sun, moon, and stars (constellations); the ability to protect represented by the mountain; the ability to be adaptable represented by the dragon; literary refinement represented by the pheasant; purity represented by the water weed; filial piety represented by two sacrificial cups; the ability of the emperor to feed the people represented by the plate of millet or grain; brilliance represented by fire or flame; the power to punish represented by the ax; and the power to discriminate between right and wrong represented by the fu symbol. Groupings and placement of these symbols also had meaning. The sun and moon placed at the shoulder and the stars and mountains at the chest and back represented four important annual sacrifices that only the emperor could make. The fu symbol and ax groupings represented the emperor’s authority over the natural worlds. The five elements of the natural world were also represented with a grouping of the mountain (earth), waterweed (water), flame (fire), sacrificial cups (metal), and plate of millet (wood or plant life).

Rank or insignia badges to indicate the rank of military and civil officials were also regulated by Qing sumptuary laws. Qing rank badges were square and were sewn to the upper back and chest of the pu fu or surcoat worn over long robes. Because the pu fu opened down the center front, Qing insignia badges to be worn on the front chest were made in two halves.

Men in the Qing court wore three basic types of robes. The most formal court robe was the qao fu (chao fu), a one-piece, dragon-figured robe with a pleated skirt attached at the waist and horse-hoof cuffs on the sleeves. Qao fu is believed to have been cut down from Ming dragon-figured robes. The heavily embroidered pi ling, or cloud collar, was worn with this robe. The qi fu (chi fu or long pao) was a semiformal dragon robe worn for festive occasions and is the robe that is usually considered as the Qing “dragon robe.” It was in the typical Manchu style, having no pleats, horse-hoof cuffs, and side and center front and back slits (women’s robes had only side slits). The pu fu with insignia badges was worn over the qi fu. Wives of officials (whether Han Chinese or Manchu) were also allowed to wear their husbands’ insignia badges. The third type of robe worn by middle- to upper-class men was the qang fu (chang fu, chang pao, chang shan, or cheong sam), an ordinary robe worn for informal occasions. This robe was generally not embroidered and was often worn with the ma kua (ma gua), or short jacket.

For women the rules of dress were more relaxed, particularly for Han Chinese women, and distinct visual differences existed between Han Chinese and Manchu women’s dress. Han Chinese women typically had bound feet, wore a two-piece garment (a jacket and long pleated skirt or trousers), maintained regional hairstyles, and continued using embroidered sleeve-band cuffs instead of the horse-hoof cuff. Manchu women wore the feminine version of the Manchu long robe, the one-piece qi pao (chi pao or cheong sam), and wore the distinctive Manchu black cloud headdress or liang pa tou erh, the “two handle headdress,” a hairstyle formed by using real or false hair built over a frame to form symmetrical wings on either side of the head. Manchu women, for whom foot binding was forbidden, wore shoes with high platform soles that emulated the gait and the small pointed toe of the Han Chinese lotus slippers. Han Chinese women did not appear to borrow many Manchu dress traditions; Manchu women, however, frequently borrowed Han Chinese dress elements, such as the embroidered sleeve bands.

Everyday dress worn by the lower classes in the Qing dynasty was simply cut and decorated. The sam fu, a two-
piece ensemble, was worn by men, women, and children. The *sam* was a long- or short-sleeved, hip-length jacket that closed to the right, and the *fu* was a pair of trousers. These were usually made from wool, hemp, or cotton fabrics and could be lined, quilted, or padded for warmth. These garments were cut to be comfortable and to allow the wearer to work efficiently. By the end of the Qing dynasty *sam* for men used a center front closure.

**Adoption of Western Clothing**

After the overthrow of the Qing dynasty in 1912 Chinese citizens began to wear Western clothing, and its adoption was particularly strong in coastal urban areas. Chinese businessmen who dealt with Westerners on a daily basis were the first to cut their queue and to adopt total Western dress. More typical was the incorporation of Western dress with traditional clothing, such as wearing the *qang pao* (*cheong sam*) with Western hats, shoes, and a suit coat. Men in rural areas were less likely to adopt Western clothing.

Urban women in China also embraced Western dress, especially hairstyles and shoes, and many totally abandoned traditional clothing. Most urban women wore modernized versions of the jacket and skirt; the *qi pao* became popular and was styled after Western silhouettes and hem lengths. Peasant or lower-class women in urban and rural areas continued to wear the *sam fu*.

Revolutionary political leader Sun Yat-sen, the “Father of the Nation,” was responsible for encouraging Chinese men to Westernize their clothing by wearing a suit based on European military uniforms and Japanese cadet uniforms. This suit had Western-style trousers, and the jacket had a convertible collar, four patch pockets, and a five-button center front opening. In the 1920s and 1930s civil servants wore this suit, and it was also modified into a military uniform worn by the Chinese army during World War II.

After the rise of the Chinese Communist Party and its leader, Mao Zedong, in 1949, many restrictions on apparel were instituted, and people were allowed to own only a small quantity of clothing. The *qi pao* was eventually considered not representative of Chinese ideals and banned from the mainland. For men and women Mao favored the suit developed by Sun Yat-sen, naming this jacket and trouser combination *chien fang i fu* or “liberation dress” and instituted this ensemble as Chinese national dress. Called the “Mao suit” or the “Mao tunic,” this uniform was believed to be in keeping with the Communist

The “dragon robe” of an emperor. Although robes with dragons as the main design existed as early as the Tang dynasty and were worn by imperial and high-ranking officials of each successive dynasty, the Qing was the first to regulate the use and possession of the dragon robe as a court and official costume. PHOTO BY JOAN LEBOLD COHEN.
precepts of universal comradeship and equality. Although the government approved other articles of clothing, the Mao suit became one of the world’s most recognized national costumes. It was usually made from blue cotton twill fabrics, although often wealthy Chinese had hand-tailored Mao suits of luxury wools.

The Mao suit was the dominant Chinese style in clothing until after the death of Mao. In the decades after his death clothing restrictions in China relaxed as the result of changes in government policies and the introduction of capitalism. As many young Chinese became exposed to the West, many of them began to wear Western clothing; soon the Mao suit was seen only on older people and people who lived in rural areas. Ironically, as the Mao suit has become less popular on the mainland, it is enjoying a resurgence outside China. Called the “Zhongshan suit,” the suit now honors Sun Yat-sen. Many young Chinese nationals living outside of mainland China often wear the Zhongshan suit as a way to declare pride in their national identity, and the suit is available through retail and Internet sources. Because of its association with Sun Yat-sen, the suit is considered to be a symbol of patriotism, and meaning has been attached to the style components of the jacket. For example, the four pockets of the jacket represent four essential principles that should guide behavior and conduct—propriety, justice, honesty, and a sense of shame. The five buttons of the center front closure represent the five government branches created by the constitution of the republic—executive, legislative, judicial, examination, and censorate. The three buttons on the cuffs represent the Three Principles of the People—nationalism (the right of the Chinese people to govern themselves), democracy (the right to have a republican form of government with elected officials), and people’s livelihood (the equalization of land and wealth to allow all people to be able to earn a livelihood). The Zhongshan suit has been the subject of many art works and is considered by many to be a cultural icon.

Just as the Zhongshan suit has become an expression of cultural identity, an interest in Han fu or “ancient clothing” has also emerged. Han fu is the traditional clothing worn during the Han Chinese dynasties—most notably the Han and Tang dynasties—and includes the one-piece, spiral-wrapped robe, the straight robe, traditional skirts and jackets, and hats, shoes, and accessory items. The phrase “Han fu” is derived from the Book of Han, which described Chinese court clothing during the Han dynasty as “delighting” visitors. The wearing of Han fu is encouraged for historical reenactments, as a hobby, and for rituals and services (such as university graduations); some Han Chinese even promote Han fu for everyday dress. For many of the Han Chinese ethnic group, the interest in promoting Han fu is a reaction against the presumption of the Manchu qi pao (cheong sam) as the representative Chinese garment.

China plays an important role in apparel manufacturing for Western companies; much of the clothing sold in the United States is made in China. The design sector of the fashion industry is experiencing growth as many young Chinese designers, trained in European fashion schools, return to China. Using traditional clothing as inspiration, Chinese designers, with their unique design aesthetic, are working to establish China as a major fashion center.

Further Reading
Although traditional Qing dynasty clothing such as the changshan (long gown) is rarely seen outside of ceremonial occasions, the more recent cheung sam (long dress) continues to be worn in Hong Kong. Made of silk, cotton, or, recently, rayon, the cheung sam is still the uniform for many Hong Kong schoolgirls and is worn on a daily basis by many older women.

In Hong Kong, a remote and unimportant regional province during the Qing dynasty (1644–1912) men wore a silk or cotton changshan (long gown), which fastened with buttons and loops on the right side, with a stand collar. Garments for winter were wadded or lined with fur. Women wore the ao, which was a knee-length changshan-like dress, and a full-length, paneled skirt with side pleats or godets (insets of cloth placed in a seam to give fullness) to allow movement. Later the embroidered part of the skirt below the ao was plain black or another dark color. Ku, which were loose, baggy trousers, were worn under the ao and continued to be worn without the skirt by female workers. Middle- and upper-class women’s accessories included an embroidered headband that hid the plucked forehead, bound-foot shoes, and ankle covers. The changshan and women’s qun gua (skirt and jacket) and dajinshan (blouse with large lapels fastened with buttons and loops) became ceremonial dress during the twentieth century. In the 1960s and 1970s heavily embroidered versions were fashionable when shops sold or rented the changshan magua (long gowns and short jackets) for men and qun gua (gua, red, front-opening jacket; qun, long, black skirt) for women. Red jackets embroidered with longfeng (dragon-and-phoenix motif), flowers, mandarin ducks, and plants later became popular bridal dresses with zisundai (offspring bands), two decorative sashes embroidered at the center of the lapel.

After the Qing Dynasty

After the Qing dynasty the qipao or cheung sam (long dress or Manchu gown) and magua (horse jacket), originally a man’s short jacket, were worn. The slim-fitting jacket had tight-fitting sleeves, side slits, and a high collar. The cheung sam became tailored using bias-cut fabric molded to shape and darts for a closer fit, with a right-front-fastening, glue-stiffened, contrasting satin binding. The cheung sam, signifying urban modernity, was accessorized with Western makeup, hairstyles, stockings, and high-heeled shoes. Girls who wore tight-fitting cheung sam in advertisements and prewar Shanghai linked the cheung sam with fashion, overseas Chinese, and Hong Kong, where it was popular. The cheung sam, a symbol of Chinese decadence after the Communist revolution (1949) and banned during the Cultural Revolution (1966–1976), became tighter and shorter, reflecting both Western fashion from the 1940s through the 1960s and Chinese uniformity. The cheung sam was universally worn, its tightness varying depending on the wearer’s position in society, modestly concealing the arms, neck, and legs. Variations

© 2009 by Berkshire Publishing Group LLC
included sleeveless cheung sam; shoulder pads; zippers set in the side slits, which were lowered en route to work and raised in a club or bar; full-length for evening wear and shorter for everyday use. Fabrics included rayon brocade, silks, and printed cottons. The cheung sam continues to be worn today as a dress-up item by actresses and some local people at Chinese New Year. A few older women wear the cheung sam on a daily basis, and many wear it on special occasions. A plain, woven-cotton cheung sam is the much-disliked uniform of some girls’ schools in Hong Kong.

The loops and buttons used to close garments were made from bias-cut strips of glue-stiffened satin reinforced with an iron wire: huianiu for women’s wear and luosiniu for men’s wear. They were featured in one, two, or three colors matched to the garment and its trimmings. Patterns included birds, fish, flowers, or insects, symbolizing Chinese characters with auspicious meanings, and reflected the tailor’s taste. Each huianiu comprised the male knotted end (gong) and the female eye (na). The same-sized huianiu are used on women’s gowns, whereas

Ladies wearing traditional Hong Kong qipao dresses. By the end of the Qing dynasty in the early twentieth century, women in Hong Kong signaled their urban modernity by accessorizing traditional clothing with Western makeup, hairstyles, stockings, and high-heeled shoes.
men’s gowns have a larger gong and a smaller na stitched near the shoulder.

**Bound-Foot Shoes**

Bound-foot shoes were usually made by the wearers: Wealthy bound-foot women were common at one time but are now uncommon in Hong Kong. Having learned to embroider, women learned to make shoes at age eleven or twelve. They embroidered the cutout parts of the shoe before assembly. The sole was made from bamboo culm, washed, straightened, bound with layers of cloth, and stitched together with a thin linen rope. Winter shoes were lined with cotton wool. Heels were made from lychee tree wood or carved pomegranate or wrapped in fabric. These were self-made or bought from vendors of wool and string. Fake bound-foot shoes, designed so that a viewer at first glance would mistake the heel for the ankle, were worn by women who wished to look as though they had bound feet.

**Minority Peoples**

The Hoklo people of Hokkien or Fujian origin wear traditional clothing for festive occasions: Whereas everyday clothing is dark, festive clothing is bright. Children’s garments and accessories, such as baby carriers, are decorated with beads, bells, decorative trims, and

embroidery, and boys' hats are made in animal shapes to confuse evil spirits. Cotton waist purses are appliquéd with bright thread. The Tanka, Hong Kong fishing people, also make brightly colored items, including baby carriers. Hakka women wove hemp during the early part of the twentieth century, making narrow braids, huadai, on waist looms. These formed straps to keep in place their liangmao—a blue or black cloth, fringed, flat, circular, bamboo brimmed hat. Hemp, handspun on a bamboo pole, was woven to make blouses and dyed by boiling yam and dyer's weed or in Kowloon's commercial dyehouses.

Contemporary Revival

Contemporary fashion designers and design students looking for new ways to wear old fashions regularly revive the cheung sam. Occasionally international fashion adopts the cheung sam, most recently in 1997, when the collection of Christian Dior included versions. New York designer Vivienne Tam, who is popular in Hong Kong, has made the most successful use of ethnic dress. Reappropriation via New York seems to be a crucial element in her success.

Decline of Ethnic Clothing

Women still wear a simplified phoenix-and-dragon robe at many weddings, but a strapless version of the Western white wedding dress—with a padded bust, tight waist, and hoop skirt—has replaced the red wedding dress, although a red evening dress (one of five changes of dress) is worn at a reception. Generally among Cantonese and minority peoples in Hong Kong the use of ethnic clothing has declined.

Taiwanese traditionally made their clothing from materials at hand, such as jute, pineapple fiber, taro flax, and banana fiber, and later from cotton cloth brought from mainland China. Clothing trends in Taiwan changed in reaction to occupation: by the Dutch (1624–1662), the Chinese in the late Ming and part of the Qing dynasties (1662–1912), the Japanese (1874–1945); and then Chinese Communists.

After the expulsion of the Dutch and a period of occupation (1662–83) by Chinese still loyal to the Ming dynasty, the Qing dynasty formally annexed Taiwan in 1683, and the Taiwanese adopted mainland Chinese fashions as many indigenous Taiwanese groups were assimilated into mainland emigrant society.

The Musée de l’ Homme in Paris displays the dress of the remaining Puyama and Paiwan tribes of southwestern Taiwan, dating from approximately the 1940s. The man’s black cotton top was made of rectangles of fabric with embroidered edges, fastened with frog fastenings and silver buttons. Multicolor leg coverings, made of strips of fabric, featured insets of indigo-dyed double ikat (fabric in which yarns have been tie-dyed before weaving) around the crotch. A waist tie of braided linen with embroidered ends and fringing was attached to the top of the leg coverings and tied twice around the waist. Also displayed at the museum is a rectangular linen cape—probably a woman’s mourning cape. The cape was made in three sections, with a cream background with red double stripes and edging. A padded headband resembling a turban completes the outfit.

Taiwanese men during the Qing dynasty wore the zhanpao (long robe) and magua (horse jacket) under an outer jacket, or gua (vest). Men wore the zhanpao, which was shorter than the gua and extended to the middle of the abdomen, with a “melon rind” skullcap. Officials wore long “python gowns” under a short gown (guazi). The guazi was longer than the gua and resembled a windbreaker jacket. Men wore these clothes in contrasting color combinations: dark or light green, blue, gray, white, or red. Manual workers wore a shan (shirt) and trousers, together known as dangshan, with a bamboo hat.

Women also wore the zhanpao, which fastened on the left and right and was decorated with brass bells and embroidery on both arms, with geometrically embroidered hand covers tied with cerise (moderate red) braids. Leg coverings were made of indigo-dyed fabric with a double-ikat spot motif, which also decorated the below-knee-length apron/skirt. The skirt had vertical bands of royal blue, indigo-dyed edging, and a central panel of embroidery in red, black, and blue. ‘Set in below the waist was an older band in blue, brown, and red fabric, suggesting fabric was precious and was reused where possible. Women also wore conch-shell necklaces.

For formal wear women wore the tadaoshan, a wide-sleeved, tight-fitting jacket trimmed with ribbon, and the mamian chun (long skirt). They wore gu (silk trousers) for formal occasions and for everyday wore a cotton version accessorized with a headband and bound-foot shoes.
Popular for women's dress were contrasting shades of red, including carmine, peach, and pink.

**Influence of Western Dress Following Japanese Trends**

Although the Japanese made little effort to introduce changes to Taiwanese dress apart from banning foot-binding, the appropriation of Western dress by the Japanese was emulated by the Taiwanese, as Western dress represented a forward-looking ideology. Western dress was combined with Chinese dress in the late nineteenth and early twentieth centuries when Han Chinese men in Taiwan wore the *zhangshan* with Western leather shoes and hats. In 1911 Taiwanese and mainland Chinese men cut their queue (a braid of hair usually worn hanging at the back of the head), and women adopted Western-style leather shoes worn with the traditional pants and jacket. By the 1920s, as Western dress increasingly replaced traditional Taiwanese dress for women, silk stockings and knee-length skirts worn with traditional short-sleeved velvet jackets, a handkerchief, and a parasol became fashionable. However, differences between the Han Chinese (who originated in Fujian or Guangdong [Hakka] provinces) continued: The Hakka preferred simple, decorative but durable materials, whereas Fujian styles were more intricate and lavish.

**Influences of China and Japan**

During the Ming and Qing dynasties imported Chinese cloth was used for garments because Taiwan had no sericulture (the production of raw silk by raising silkworms), and grew little cotton or hemp. Locally produced fibers were colored with chemical dyes, which replaced plant dyes. Pineapple fiber, jute, taro flax, and banana fiber were also used. After 1918 Japanese spinning and weaving technology was imported, and large-scale production used Japanese cotton for everyday wear, eventually replacing Chinese imports. After two or three decades of occupation, Japanese fabric patterns and the pale “refined” colors favored by the Japanese (lake green, grayish blue, pink, baby-blue, and beige) became standard and replaced the bright colors and patterns of the Qing dynasty. After Japan declared war on China in 1937 the Japanese attempted to weaken Chinese cultural links and fashions in Taiwan: Although older men continued to wear traditional dress, young men adopted military uniforms, *muge* (Japanese wooden clogs), and “duck’s tongue” hats—a wider version of the Western cloth cap. Women wore the kimono. As on mainland China, children dressed like small adults: Cloaks and hats had decorated hems, tassels, and embroidery for special occasions; pants had split seats; and in 1925 Western-style school uniforms were introduced.

The popularity of the *qipao* or *cheongsam* (in Cantonese), the asymmetrically fastened dress worn by women, peaked between the 1940s and 1960s. The Sun Yat-sen suit (named for the Chinese revolutionary) became unfashionable after mainland Chinese Communist rule was established in 1945 but was worn formally by some Republican (Republic of China) government officials, tailored in khaki-colored wool, with breast pockets and military-style brass buttons, flaps, and a high collar.

In the mid-twentieth century on special occasions the *hong gua*, a red embroidered jacket and a black embroidered skirt featuring dragon and phoenix motifs, was worn with a headdress. For special occasions in rural areas, men wore a traditional blue gown with a diagonal red sash and gilt hat sprays on each side of a skullcap or trilby hat. During the 1960s and 1970s, as Western fashions were adopted, these fashions declined in popularity.

Tibetan costume reflects the environment and lifestyle of Tibet’s people and plays an important role in regional, familial, and individual expression. Tibetan traditional clothing is characterized by the dual purpose of being aesthetically pleasing as well as functional.

Influences from Abroad

Traditional Tibetan costume was influenced by the custom of exchanging tribute gifts between Chinese and Tibetan nobility. Chinese silks are believed to have been given to the Tibetan emperor Songtsan Gampo by the Tang emperor in 649 ce. Other Chinese costume characteristics, such as color symbolism and the right-over-left closure method, are also reflected in Tibetan costume. Tibetan and Mongolian traditional costumes also share characteristics; in particular, lamas of both countries share similar costumes, among them the zi xia (crested helmets).

Fabric and Color Choices

Fabrics used for Tibetan clothing include hemp, Chinese cottons and silks, rayon, satins from India, indigenous animal furs, felted fabric derived from the hair of the yak, and pulu, a traditional woolen cloth. Pulu was a popular tribute cloth given to China.

The weight and type of materials used for clothing varies with the climatic regions of Tibet. Daily temperatures fluctuate greatly, and Tibetan garments are worn layered, which allows adjustments for comfort. Although there are regional stylistic variations in Tibetan garments in embellishment, materials, and colors, the basic pieces are similar and worn by both men and women.

Tibetan costume is characterized by the use of strong, unrestrained, dramatic color combinations. Strong contrasts in color combinations are made harmonious through the use of white and black bindings at clothing edges and elaborate gold and silver embroidery across the surface of the garments. Common color contrasts used in Tibetan clothing are white and black, red and green, orange and blue, and yellow and purple, colors that also reflect the influence of Buddhism.

Typical Garments

The most distinctive Tibetan outer garment is the chuba, a loose-fitting robe made of sheepskin or pulu. The pocketless chuba closes to the right and is tied at the waist with sashes or belts. The sleeves on the chuba are long, often reaching to the knee. The chuba may be as long as seven
feet, and the upper part is bloused over the waist ties to adjust the length to knee level for men and ankle level for women and priests. The extreme length of the chuba allows the robe to be used as a blanket or sleeping bag. One or two leather belts or sashes are used to keep the chuba in place. When the upper part of the robe is pulled over the waist ties, a pocket is created that is used to hold objects or form a child carrier. Waist ties also keep the robe in place to allow the wearer to pull out his or her arms for cooling. Typically, the right arm is worn uncovered by the robe. This has become known as the Tibetan style and is one of the most culturally distinctive style characteristics of Tibetan costume.

Many styles of chuba are specific to occasion or region. Styles include the guxiu, a sleeveless, broad-shouldered robe made of black pulu or animal skins, and the giubjialo, a lined pulu robe with a floral design on the collar. The cha is a fur-lined robe worn by men and is made either from jacquard silk fabric (for special occasions) or plain-colored leather (for everyday wear).

Women’s garments include the anju, a long-sleeved top made of plain or printed silk, cotton, or rayon. This is often worn with a skirt and an apron (bangdian). Another garment worn over the anju is the anduh, a full-length, sleeveless dress usually made of black pulu and lined with blue fabric.

Various styles of vests and jackets constructed from a variety of materials are worn by both men and women. Men and women also wear leggings tied to a waist girdle.

Costume indicates a woman’s marriage status. Married women wear the bangdian, an apron that varies in style from region to region. Usually rectangular, bangdian are constructed from three widths of fabric sewn together vertically. Each narrow fabric width is hand-woven wool or silk fabric, horizontally striped in shades of primary and secondary color combinations. Another style is a plain-colored bangdian made from blue, black, or gray cotton or pulu cloth. In some areas plain cloth and striped fabrics are used together.

Different hairstyles and hair ornaments are also important marital indicators and vary by region and tribe. An important style characteristic is the symmetry of the hairstyles and ornaments in the hair. One very distinctive regional hairstyle for married women is the peyrak, a Y-shaped style, in which the hair is curved into two ram-shaped horns encircling the head. Women’s hair is also embellished with many hair ornaments of precious metals and materials.

**Standard Accessories**

Accessories are important in Tibetan costume, serving decorative and practical purposes. Silver belt buckles and belts are common for both sexes. Many accessories hang from the waist ties. Males typically hang swords, Buddhist boxes, cartridge clips and belts, and bagu (metal wallets) from their waist ties or belts. Women often hang needle cases and small household implements from their waist ties.

Both men and women wear jewelry such as earrings, bracelets, and necklaces. Men might wear only one large dangling earring. Turquoise, agate, coral, jade, amber, silver, and gold are highly prized jewelry materials. Women wear more jewelry than men do. Part of the wealth of the family is kept in women’s jewelry, and women often wear large amounts of very large and heavy jewelry pieces.

One of the most important accessories worn by women is the kou, or gau, a square metal box with a diamond shape on it. The kou contains a Buddhist religious artifact and is worn around the neck on a chain so that it rests on the woman’s.

Square-toed boots (sunpa) are a popular type of footwear. Sunpa have soles of thick yak hide with leather or fabric foot and leg sections. They may be embellished with embroidery. Sunpa lace or tie up the back.

Headwear is also an important part of Tibetan costume, and the shape and quality of the hat indicate rank, status, and regional and tribal affiliation. The xiamou jiasi (golden flower) hat is worn in winter by men, women, and children. The xiamou jiasi has a tall crown of fabric, felt, or leather, and four fur flaps. It is often trimmed with gold rickrack imported from India or China.

The kata, or khata, is an important Tibetan textile material artifact. It is a white scarf symbolizing purity that is offered as a gift when greeting people. Kata is also used as an offering when visiting shrines and during other rituals such as wedding and funeral rites. This tradition is believed to have evolved from an ancient custom of clothing statues of deities.
Changes in Fashions

Changes are occurring to Tibetan costume, probably because of exposure to Western clothing styles. Although strong colors are still preferred, some of the traditional dramatic contrasts have been replaced in some areas with strong matching colors, often in single-color schemes. Another change is in the fit of Tibetan robes. Robes are being fit closer to the shape of the body. This silhouette modification is particularly evident in women’s clothing. Still another change is in the wearing of bangdian. Originally worn only by married women, unmarried girls and women have started to wear the bangdian for special days and celebrations.

Exposure to Western clothing has also resulted in some Tibetans wearing Western clothing exclusively. Other Tibetans wear a combination of Western and traditional styles; for example, men wear the chuba with Western style shoes. Traditional clothing is still worn exclusively in less populated regions.

Traditional clothing is recognized as important to the culture and unique to the people and the region. Local tailors promote the use of traditional clothing for women, believing that traditional styles best showcase the beauty of Tibetan women. Traditional clothing worn by local people is an important tourist attraction, and many visitors to Tibet purchase traditional clothing items as souvenirs. Tibetan traditional clothing has also been recognized as a source of design inspiration. In recent years modern designers, such as Wu Haiyan from China, have created high-end fashion lines inspired by the distinctive clothing styles from the “roof of the world.”

The Committee of 100, which actually has more than 150 members, is an organization of prominent American citizens of Chinese descent that works to bridge U.S.–Greater China relations.

The Committee of 100 is a national, nonpartisan organization whose members are American citizens of Chinese descent. It was founded in 1990 by leaders in the Chinese-American community who saw the need for an organization that would bring a Chinese-American perspective to relations between Greater China and the United States; they envisioned an organization that would address the concerns of Americans of Chinese heritage. The members, who have achieved prominence in a broad range of professions, pool their strengths and experiences to further the goals of the organization.

The Committee of 100 has a twofold mission. It is first concerned with bridging the gap (and strengthening relations) between the United States and Greater China. In addition it encourages Chinese-Americans to participate in all aspects of American life. During the 1990s the committee's efforts were primarily focused on this second purpose, but as China has changed, so too has the Committee's mission. Now the committee wants to be seen as a cultural ambassador in the exchange and sharing of perspectives, ideas, and experiences among all those concerned with Greater China-U.S. relations.

Many of the committee's members are involved in academics, government, business, law, science, and the arts. Its founders include the cellist Yo-Yo Ma; Shirley Young, a senior adviser to General Motors; the architect I. M. Pei; and Oscar Tang, an investor and philanthropist. The committee has more than 150 members.

Recognizing that highly skilled, well-educated individuals are essential to China's continued growth and prosperity, the Committee of 100 has established endowment funds to provide scholarships for outstanding students and teachers at several universities in China. In conjunction with its annual conference, the committee, since 2003, conducts mentoring events for students and young professionals. Each mentorship event provides young professionals, the next generation of Chinese-American community leaders, the opportunity to connect with committee members who are prominent leaders in their fields. Participants at each event are able to learn directly from committee members who share their personal experiences, successes, and challenges. Participants also discuss their unique issues with members.

In 2006 the committee introduced a mentoring website, www.c100mentoring.org, to provide another portal for participants and to serve as well as a resource for those unable to attend a mentoring event. The site consists of essays on career advice written by members.

In addition to its mentoring efforts, the committee regularly conducts opinion surveys in order to provide objective data on the mutual perceptions of American and Chinese regarding such subjects as economics and trade, product safety, environment and climate change,
American Attitudes Toward China

A survey conducted by the Committee of 100 in 2004 examined American opinions about China.

American attitudes toward China have improved significantly over the past 10 years since the Committee of 100’s study in 1994, indicating that 46% of Americans view China favorably versus 59% in 2004. Also, familiarity with US-Chinese issues by Americans has grown. Further, Americans expect US-China relations to continue improving.

Despite American concerns about job losses and outsourcing/off shoring, the benefits of China’s low cost products appear to outweigh the negatives even among union members and those that have lost jobs (who do not blame China).

Compared to 10 years ago, China is now viewed as much more of an economic vs. military threat. China is viewed as an ally by significantly more Americans (48% of the general public) than 10 years ago (25%). However, China’s support of the US in the War on Terrorism is not well known nor recognized by either opinion leaders or the public, with only roughly 30% of both groups viewing China as a dependable ally in the War on Terrorism.

Human rights remain the key concern by Americans towards China with its impact on the global environment - being registered as a second key concern by opinion leaders and fourth by the general public.

The overall trend of increasingly positive attitudes toward China may influence American attitudes towards Chinese Americans. In contrast to a Committee of 100 survey, “American Attitudes Toward Chinese Americans and Asian Americans,” conducted in 2001, this study reflects a positive shift in attitudes toward the immigration of Chinese to this country. Another interesting finding was that the 23% of respondents who claim to have family or friends who have adopted a Chinese baby could suggest that increasing numbers of Chinese adoptions has an impact on American attitudes towards China and the Chinese people.

and Taiwan. Public opinion plays a significant role in shaping government policymaking and forecasting the direction of bilateral relationships. Over the years the survey results have been relied upon by the media, opinion leaders, and decision makers.

The Committee’s headquarters are in New York. It also has an office in Hong Kong.

Committee on Scholarly Communication with China

Zhōng-Měi Xuéshù Jiāoliú Wěiyuánhuì
中美学术交流委员会

The Committee on Scholarly Communication with the People's Republic of China, known since 1996 as the Committee on Scholarly Communication with China (CSCC), was founded in 1966 and is devoted to fostering and promoting academic relations, research, and exchange programs between American and Chinese students and scholars.

In 1966, the United States National Academy of Sciences (NAS) partnered with the American Council of Learned Societies (ACLS) and the Social Science Research Council (SSRC) to jointly sponsor the Committee on Scholarly Communication with the People's Republic of China (CSCPRC), with a new office in Washington, D.C.

The decision to develop a committee on China came mainly from the NAS, after China successfully detonated an atomic bomb in 1962. This success caught the attention of American scientists and in 1963 the NAS convened to discuss the establishment of a China committee. In an effort to provide American China specialists with access to China and provide better communication among scientists from the two countries, the NAS decided to focus the committee mainly on the natural sciences, though some attention was also paid to the social sciences and the humanities.

The CSCPRC was formed at a time when such communication was not routine. Years of an estranged relationship finally began to tentatively resolve in the early 1970s, when a visit from President Nixon initiated the United States and the People's Republic of China (PRC) to sign an agreement to amend academic ties nearly a decade after the CSCPRC was formed. However, it was not until long after the Tiananmen Square incident in 1989 that the academic relationship between the two countries developed into the free flowing current of ideas seen today.

The first signs of an improved relationship between the two countries came with President Nixon’s visit to China in 1972. The event led to the organization of approximately 67 delegations between the two countries over the course of a month, covering topics mainly in the natural sciences such as herbal pharmacology, linguistics, seismology and early childhood education. Though delegations that focused on the social sciences and the humanities did occur, a greater interest was held with studies in technical and natural sciences. The reports written and published from these delegations marked the beginnings of Chinese research institutes and filled a gap in American knowledge of Chinese science. Also in the 1970s, reassurances from Mao Zedong that Chinese-American scientists were welcome in China helped keep the exchange of people and ideas flowing, and soon US industry leaders Exxon and IBM were openly welcoming Chinese specialists.

As the work of the CSCPRC grew during the 1970s, the idea of reciprocity of ideas and scholars, and eventually of students, was greatly enforced. In 1978 US-China political relations moved more toward normalization and...
a proposal was made by President Carter’s Science Advisor, Frank Press, to exchange ten students from each country. Vice-Premier Deng Xiaoping then proposed that China send 500 students and scholars to the United States the next year.

The CSCPRC often encountered problems with the exchange of students in early years. The U.S. was denied a centralized office in China to aid in placement of American students, and was forced to go through Chinese agencies like the Ministry of Education (MOE). Finally, in 1986 the Committee received permission from both U.S. and Chinese officials to open an office in Beijing. This new office was sponsored by the Chinese Academy of Science (CAS) and facilitated programs to help coordinate placement of students and scholars in China.

For thirty years the CSCPRC helped develop and foster academic ties between the US and China, and the main responsibility of the committee came from the NAS. In 1996, however, ACLS President Stanley Katz announced that budget restrictions and a decline in private and federal support forced the closure of the Washington, DC office of the CSCPRC, now renamed the Committee on Scholarly Communication with China (CSCC). When the Washington office closed, the Slavic, East European and Asian Reading Room (SEEARR) of the Gelman Library of The George Washington University received the CSCPRC’s Washington-branch library as a donation, along with its corresponding non-administrative information files. These information files comprise 96 boxes of material organized by subject-matter and further organized chronologically into colored file folders.

Working out of the Beijing office, the Committee still serves as a link between the NAS and the CAS and, thanks to the Committee’s long experience fostering such relations, remains a preferred route for students and scholars pursuing research and studies in China and in the United States.

Further Reading

External communication refers to broadcast information that is meant for a foreign audience. Similar to the United States’ Voice of America and the BBC’s world services in the U.K., China employs a vast array of media outlets (in dozens of languages, in addition to Chinese) to project a positive image to the world, with varying degrees of success.

External communication in China, often termed duiwai chuanbo 对外传播, refers to news reports and other communication activities that aim to enhance better understanding and promote a favorable image of China among global audiences via media channels such as radio, TV, newspapers, news agencies, and websites normally run by Chinese organizations inside China. These efforts are similar to the Voice of America in the United States and the British Broadcasting Corporation’s world services in the United Kingdom.

Since the concept of external communication is so frequently related to China’s image around the world, external communication, since the 1980s, has become an increasingly significant topic for a country that has been eager to project itself to the rest of the world as a peaceful rising power. The idea of a China “brand” was frequently discussed in the media before the Beijing Olympics in 2008 and remains relevant to companies seeking to introduce Chinese products to global markets.

Historical Development

While external communication, or duiwai chuanbo (dui-wai means “external”; chuanbo means “communication”), is a contemporary term popular only since the 1980s when Deng Xiaoping (1904–1997) instituted China’s open and reform policies, the concept can trace its origins to the nineteenth century, when China was known as a sleeping giant (a term coined by Napoleon) and was forced by Western powers to cede some of its territory.

The idea of external communications was first initiated by Chinese intellectuals educated in the West in the late Qing Dynasty (1644–1912), which, with a strong intention to make China one of the powers in the world, came to understand that the then passive and backward status quo of China had somewhat resulted from the huge imbalance of information flow from the West and lack of sufficient information exchange and communication from China to the West and the rest of the world. Since most Westerners did not understand Chinese, it was natural for these Chinese intellectuals to resort to foreign-language publications to introduce China.

Sun Yat-sen (1866–1925), often known as the Father of Modern China and founder of the Guomindang (GMD), or Nationalist Chinese Party, paid special attention to launching news publications in and outside China during his political career. But external communication in China did not get into full swing until it was supported by the Guomindang government in 1930 when foreign-language newspapers, radio stations, and news agency were set up in China. Thus 1930 has been
heralded as the starting point for external communication in China.

External communication has since witnessed three stages of development. The first stage was from 1930 to 1949 when the GMD’s Republic of China was forced to Taiwan and the Communist Party of China established the People’s Republic of China. During this time external communication was still dominated by the GMD government in parallel with the news-related activities of the Communist Party. External communication in China did not see a peaceful transition and continuity when political power shifted. For instance, the GMD government blew up the then largest radio station in Asia (Voice of China) in Nanjing on 29 November 1949 when it left the mainland for Taiwan.

The second stage was from 1949 to 1980 when the Communist Party established external communication in China. Everything in China at that time was politically oriented, and external communication was no exception. It was during this time that external communication was, in fact, duiwai xuanchuan (对外宣传), (xuanchuan 宣传 means “propaganda”). It should be noted, however, that in Chinese xuanchuan has no negative connotation, even though it often has in the Western perspective. Chinese considered duiwai xuanchuan a neutral or even positive term, equal or similar to external communication. The term itself thus incited numerous mixed responses about China because China was then completely isolated from the outside world for political reasons.

The third stage started in 1981, marked by the birth of the China Daily, the first English-language newspaper in China since the North China Daily News. The North China Daily News, a very influential foreign newspaper, was set up by the British in 1864 in Shanghai and ceased publication in 1951. The birth of the semiofficial China Daily was a landmark for external communication in China. It deviated from the propaganda style of the party organ People’s Daily, popular during the Cultural Revolution (1966–1977), and targeted English-reading audiences, with a Chinese perspective. The birth of the China Daily also sparked a wave of English-language media, including CCTV-9 at the central level, the Shanghai Daily and the Shenzhen Daily at the local level, and more recently English-language websites in almost all the major cities in China, in addition to the expansion of existing China Radio International (CRI) and the restoration of English-language magazines that had ceased publication during the early years of the People’s Republic.

It was in this third stage that most people in China also realized the negative connotation of the English word propaganda and started to employ a more neutral term, duiwai chuanbo, or external communication, or external publicity if literally translated from Chinese. At present most scholars and media practitioners in China prefer to use external communication (even global communication or international communication) to describe the Chinese perspective of duiwai chuanbo.

Characteristics

Since it originated from a unique historical background, external communication in China has enjoyed its own characteristics, as compared with internal communication in Chinese.

As it is elsewhere in the world, external communication in China has a strong political orientation and produces media content mainly in an effort to influence global audiences in favor of China’s national interests. The ultimate goal is to promote a better understanding between China and the rest of the world. Almost all external communication activities are sponsored by the government. This is particularly true when faced with a major news event like the Beijing Olympics.

In terms of media categories as well as media content, external communication is diversified and comprehensive. In China media organizations for external communication include radio stations (CRI); newspapers (the China Daily and the Shanghai Daily); TV stations (CCTV-9 in Beijing and ICS in Shanghai); numerous magazines; and websites, such as Xinhuanet and Eastday, both at the central and local levels, normally in cooperation with traditional media organizations. In addition to daily news reports, these media organizations offer other content, including entertainment, tourism background, educational information, and services of all kinds in an effort to better cater to the needs of a global audiences. This is a very different approach from the propaganda style of the past.
External communication in China employs a number of languages in addition to standard Chinese. For instance, CRI broadcasts in forty-three languages and four dialects. The major foreign language used for external communication is English, as far as media categories and content are concerned. The English dominance of media is especially evident in the metropolitan areas like Beijing and Shanghai, which provide global audiences with a good choice of local and international media in English. However, in inland and mountainous areas, English media are still scarcely available.

Unlike the Voice of America in the United States, which is made available only to foreign audiences, external communication in China is available to not only foreign audiences but also Chinese audiences inside and outside of China. Given the size of the Chinese population, it is no surprise to find that the Chinese audience greatly surpasses that of foreign audiences, according to surveys conducted by CCTV-9 and the China Daily in 2001 and 2002. The surveys also offered a reasonable explanation for the large size of the Chinese audience: They want to use the English-language media available to them, including textbooks, to learn English rather than to consume media content.

The overwhelming enthusiasm of Chinese audiences to learn English may have diluted some of the effectiveness of China’s efforts of external communication in the world, according to the above two surveys. Despite the government’s strong support for external communication, China’s English-language media have not always received a positive response from foreign audiences. However, it should be noted that the not-so-positive survey results for external communication in China is sometimes more ideological and cultural than it is journalistic because foreign audiences, particularly from Western countries, have an inborn distrust toward media owned and operated by the government, even when Chinese journalists practice good journalistic professionalism for external communication. Except for English-speaking journalists, who often serve as English-language polishers, most staff in English-language media organizations are Chinese journalists and editors who reside in a Chinese environment. Although their English writing is communicative enough, they may still encounter cultural obstacles that, on some occasions, may confuse and even create misunderstanding for global audiences. Other reasons can also be cited, but it remains true so far that external communication in China has not been as effective as expected.

**China’s Image**

Even though external communication aims to create a favorable image of China as a nation, China’s image has not really been portrayed by these media for external communication inside China. Rather, the projection of China’s image in the world has been heavily influenced by writings about China by Western authors and news coverage by Western media, which tend to play up or ignore different elements of the real China, inevitably from a Western perspective, which may seem critically negative and unfriendly to most Chinese.

As a result, China’s image in Western media is generally accompanied with such key phrases as democracy, human rights, and freedom of the press, leading to a climax during the torch-relay demonstrations in 2008 when China hosted the Beijing Olympics.

In 2004 the Chinese government initiated the first of many Confucius Institutes (in Seoul, South Korea) to address growing interest in China and the international demand for Chinese language instruction; by 2009, there were 307 such institutes in seventy-eight countries. Reaction to the Confucius Institute vary. There is concern about the institutes’ sponsorship by the Chinese government; some universities and individuals fear that this sponsorship could lead to undue government influence on curricula within Asian studies departments.

While part of China’s image may be based on Western biases and lack of sufficient knowledge, discussions of China’s image have helped China open up to the world and contribute to its social improvements in the past three
decades, particularly after China successfully hosting the Beijing Olympics. External communication, though perceived as ineffective in building China’s national image, is still considered an important part of China’s global interaction with the rest of the world.

**Challenges**

External communication is still regarded as a unique concept in China but reasonable and necessary because of China’s historical, linguistic, and ideological isolation in the past, and differences between external communication (mostly in English) and internal communication in China. The uniqueness of China’s external communication system is best illustrated by the media practice and rule of *neiwai youbie* 内外有别, which means “keep external communication separate from internal Chinese communication.” As a result, China has established two kinds of media systems for the two forms of communication systems, each with its respective target audiences, funding channels, personnel recruitment, and even journalistic styles and guidelines. But as China has become more global and mature in its market economy, particularly since the Beijing Olympics, it has become more difficult to maintain the practice of *neiwai youbie*.

China will most likely have to merge the two sets of communication systems in the future, but it remains a question as to when and how it will take place.

**Further Readings**

Established in the 1920s, the Youth League has been the training ground for the Chinese Communist Party for the last eighty years. With over 86 million members, it has been a route since the 1980s for leaders to enter the top echelons of the party, and is one of the most influential groups in China.

The Communist Youth League (CYL) was established in Shanghai as the Socialist Youth League of China in 1920, a year before the first congress of the Chinese Communist Party (CCP), an organization that the CYL's history has shadowed. When the CYL held its first congress in 1922 in Guangzhou (Canton), one of the leading intellectuals of early Chinese Communist history, Chen Duxiu (1879–1942), spoke. The league changed its name to the "Chinese Communist Youth League" in 1925 and to the "Chinese New Democracy Youth League" on establishment of the People’s Republic of China (PRC) in 1949. At about this time it became more merged into the organizational structure of the CCP. It was named the "Communist Youth League" in 1957.

Suspended during the Cultural Revolution (1966–1976), the league came to greater political prominence in the 1980s, being perceived as a training ground for future high-level Chinese leaders, among them President Hu Jintao. This idea of the CYL being a “party reserve” lingers, with several of the current members of the Politburo (the principal policymaking and executive committee of a Communist party) having had positions in the CYL. The extent of its influence, however, is debated, with many arguing that the CYL's influence has been overstated.

In terms of size and structure the CYL reflects the CCP. Its 70 million members come close to the 74 million members of the CCP, with 210,000 committee members. It has a party secretary, much as the CCP does, who sits, in fact, on the Central Committee of the CCP and reports to that committee. Like the CCP, the CYL holds five yearly congresses, the last of which, in 2003, included the election of Hu Chunhua, previously a party official in Tibet (like Hu Jintao). Membership in the league is restricted to people ages fourteen to twenty-eight, with the Young Pioneers group open to those up to the age of fourteen. Like the CCP, too, the CYL has representation and separate command structures in China's provinces, autonomous regions, and cities under municipalities. The CYL operates the China Youth Daily (established in 1951).

According to its mission statement, the CYL “unites and leads youths to focus on economic construction, and doing the great practice of building socialism with Chinese characteristics, to temper themselves as successors who are well educated, and have lofty ideals, moral integrity, and a high sense of discipline.” (Retrieved from http://www.cycnet.com/chinayouth/organisms/ccyl.htm). The CYL was led from 1957 to 1978 by Hu Yaobang, who was to go on to become general secretary of the CCP in the 1980s and whose death in 1989 was one of the precipitating facts of the Tiananmen Square disturbances that year. The CYL was led from 1984 to 1985 by Hu Jintao and from 1993 to 1998 by Li Keqiang, who is a current Politburo member and predicted to be one of China’s key leaders after the retirement of Hu and Wen Jiabao in 2012.
The idea of the CYL being a training ground for elite politicians took root in the 1980s when CCP leader Deng Xiaoping elevated people with a previous record in the CYL to national positions. At the seventeenth party congress in 2007 a new group of younger leaders who had previously occupied positions in the league was elevated to the Politburo. However, the highly diffracted nature of Chinese politics now means that it is increasingly difficult to settle on clear factions. The influence of the Shanghai group, associated with CCP leader Jiang Zemin in the 1990s and early 2000s, has also been questioned. In the end the best that can be said of the CYL is that it remains an important (and large) organization under the CCP and that it is likely to continue producing political figures and being a political network. However, the CYL itself is not associated with any specific viewpoint on important policy and social issues.

Compendium of Materia Medica

Běncǎo Gāngmù 本草纲目

The Compendium of Materia Medica (Bencao gangmu; 1596) was an encyclopedic work of medicine and natural history written by Li Shizhen (1518–1593) in the last decades of the sixteenth century. Since the early seventeenth century it has become one of the most widely cited and studied books in the history of Chinese science and medicine.

An encyclopedic work of medicine and natural history, the Compendium of Materia Medica (Bencao gangmu; 1596) was written by Li Shizhen (1518–1593) in the last decades of the sixteenth century. Although the author’s own text grafts together several scholarly genres, the Compendium is best known as the result of a rich tradition of bencao literature. The term bencao has variously been translated as “pharmacopoeia,” “materia medica,” “pandect of natural history,” “pharmaceutical literature,” and “encyclopedia,” all of which approximate the nature of the genre. This type of medical text focused on the drugs used in Chinese medical prescriptions, classifying each drug according to qualities such as flavor, toxicity, presence or absence of heat, and appearance, and occasionally provided an explanation of the most common or alternate names for the substance. Bencao texts could also include discussions of the textual and natural history of each drug or debates about its properties, and for this reason, bencao are valuable sources for the study of plants, animals, and stones throughout the history of China.

The Compendium comprises fifty-two juan (roughly equivalent to chapters) and almost 2 million characters, enormous in scope for a bencao work. Of the 1,892 drugs included, 374 were added for the first time by Li Shizhen. The Compendium broke from previous collections of materia medica in the extent to which it incorporated literature from nonmedical texts (poetry, history, tales of the strange, and so on) as sources on the natural history of medical drugs. The structure of the work was based largely on Tang Shenwei’s (ca. 1086–1093) Organized and Classified Materia Medica (Zhenglei bencao), a model in its own gestures toward incorporating nonmedical scholarly texts into the service of explicating the use of plants and animals in medicine. The title of the Compendium reflected Li’s intellectual debt to neo-Confucian philosopher Zhu Xi (1130–1200): The phrase gangmu invokes the structure of Zhu Xi’s own Tongjian gangmu, with a basic macroclassification (gang) supplemented by more detailed analyses of individual entries (mu).

Contents of the Compendium of Materia Medica

Several editions of the Compendium have been published since its first printing in 1596, and most contain the same basic elements. (For a list of the contents, see table 1.) The text began with a section of introductory material, including a preface by famous Ming scholar Wang Shizhen (1526–1590), 1,109 illustrations drawn by Li Shizhen’s son Li Jianyuan and collected together in two separate juan,
a table of contents, and a preface by Li Shizhen. Li’s own short, prefatory remarks provided background on the macrostructure of the text and the logic of its arrangement, from the most elemental (water) to the most complex (humans). Li also discussed the place of the Compendium with respect to prior works of its kind as well as the reasons behind the inclusion or arrangement of certain drug entries.

Next, Li chronicled the history of bencao literature and provided a bibliography of medical and nonmedical sources consulted in writing the Compendium, along with a list of previous bencao and the number of drugs in various categories that each contained. Extended descriptions of the contents of two foundational bencao texts (both of which Li attributed to Tao Hongjing, though the authorship of the second is now questioned), the Shennong bencao jing and the Mingyi bielu, were followed by Li’s discussion of medical principles such as seasonality, organ/functionality systems, flavor, and yin and yang and their relevance to the prescription of drugs. Li followed this with a long section on the theory and practice of pharmacology, including discussions of drug interactions and a list of materials organized according to major illnesses they were used to treat.

The remainder of the text consisted of classified descriptions of individual drugs, including elemental materials such as water and fire, stones, tools and implements, plants, animals, and humans. According to Li, the logic of the arrangement progressed from the lowliest of creatures

*This list was compiled on the basis of the Liu Hengru and Liu Shanyong edition of 2002, which in turn was based on the 1596 Jinling and 1603 Jiangxi printings of the *Compendium*. The Jiangxi edition also included prefaces from Xia Liangxin and Zhang Dingsi, along with Li Jianyuan’s memorial.
to the most noble. The structure and contents of the *Compendium* were also influenced by Li’s deep interest in the five phases (water, fire, earth, metal, and wood).

**Printing of the Compendium of Materia Medica**

Li Shizhen spent more than thirty years researching and compiling the *Compendium* and spent the last decade of his life searching for a publisher. The carving of blocks for the first edition of the *Compendium* by printer Hu Chenglong finally began in Nanjing in 1593, but the work was not printed until 1596, three years after Li’s death. This first edition of the *Compendium*, known as the Jinling edition (an archaic term for Nanjing), was probably sold in limited quantities to the relatively wealthy professionals who could afford it.

Li’s son Li Jianyuan had accompanied his father along many of his travels, had drawn the illustrations for the *Compendium*, and was foundational in ultimately getting the work published. He submitted a memorial to the imperial palace in the first lunar month (January or February) of 1596, presenting the first printed copy of the *Compendium of Materia Medica* to the emperor in an attempt to obtain imperial backing for the printing of his father’s work. An account in the *Ming History* attests that the emperor admired the *Compendium*, ordering that it should be printed and circulated throughout the empire so that scholars would all have the book. However, this account is probably an exaggeration: The inscription on the manuscript in the Ming imperial library simply stated that the emperor saw the *Compendium*, the Ministry of Rites knew of it, and it would stay in the palace.

Further editions were printed in 1603, 1606, 1640, and then countless times through the twenty-first century. The 1603 Jiangxi printing included additional prefaces, along with Li Jianyuan’s memorial to the emperor. More illustrations were added in successive printings of the *Compendium*, some illustrations were significantly altered, and Qing editions began appending Li’s shorter works to the text. Zhao Xuemin’s (1719–1805) *Correction of Omissions in the Compendium of Materia Medica (Bencao gangmu shiyi)* was the most significant revision of and commentary to Li’s text. It was added as a further appendix to later editions of the *Compendium* after its initial publication in 1871.

**Current Influence in China**

The *Compendium of Materia Medica* is still studied as part of Chinese medical curricula, and modern scientists are still researching the biochemical bases of many of the drugs discussed by Li Shizhen. Partial or complete translations of the text have been published in Japanese, French, German, and English. Li was reinvented as a father of traditional Chinese medicine under Chinese Communist rule, and the *Compendium* is now typically acknowledged as a fundamental text in the history of Chinese science and medicine. Several Chinese artists
in the twenty-first century, including the installation artist Huang Yongping and the popular musician Jay Chou, have reinterpreted the Compendium in works that challenge ideas of traditional Chinese culture.

Confucian Ethics ▶
Confucian Ethics

Confucian ethics teaches that no fixed and binding rules govern the moral life. Rather, a person must be trained to weigh the relative value of actions in specific situations in regard to specific persons. Confucian ethics had a strong influence on Chinese, Korean, and Japanese cultures.

Confucian ethics, founded on the idea that people must strive to do their best to express human kindness or love for others, left an indelible mark on the development of Chinese, Korean, and Japanese cultures.

Confucian ethics can be compared with Aristotelian and feminist virtue ethics and best understood as a contextualistic virtue ethics based on self-cultivation. Three general categories are used to classify moral systems: absolutism, relativism, and contextualism. Ethical contextualism holds that there are no absolute moral rules and that cultural customs or feelings cannot be blindly followed; alleged absolute codes or customs and feelings can serve only as guidelines. Each person must decide what is the best that she or he can do in that particular context to complete an action of a higher value such as authenticity, love, or virtue. The philosophies of the ancient Greek Aristotle, the Chinese philosopher Confucius (551–479 BCE), and the existentialists, as well as and modern situation ethics are examples of ethical contextualism. Confucian ethics can be summarized as the art of contextualizing the practice of virtue.

Confucian ethics bears some similarity to Aristotelian ethics. Both are virtue-based systems (virtue ethics refers to the moral quality of a person’s character or personality as opposed to a person merely obeying moral rules) that acknowledge that no fixed and binding rules govern the moral life. Rather, a person must be well trained and habituated to weighing the relative value of actions in specific situations in regard to particular persons.

Confucians and Aristotelians soon part company, however. Aristotle held what has been called the “doctrine of the golden mean,” namely, that most of the virtues are at the midpoint between the extremes of deficiency and excess. Regrettably, Zhongyong (centrality and commonality), one of the Four Books of the Confucian canon, was misleadingly translated as the Doctrine of the Mean, allowing for superficial comparisons. The Confucian concept of “centrality” refers to the condition before feelings of pleasure, anger, sorrow, and joy are expressed; clearly it is not the mean between extremes.

Confucius and Earlier

Confucian ethics began long before the time of Confucius. It was rooted in the clan values of the early Zhou dynasty (1045–256 BCE) aristocracy. Confucius was both a traditional and an innovative thinker; he breathed new life into the traditional aristocratic clan ethics of the Zhou. His innovation was that he sought to transform aristocratic values and practices into everyday practices and values for common people. Thus, he reinterpreted the label for “prince” (junzi, the son of the ruler) to mean any

All Confucians agree that moral education begins at home. Only after a child learns filial respect for parents and brotherly love for siblings can he or she be expected to extend respect and love beyond the family. Methodologically, filial piety (xiao) is primary; ontologically (relating to being or existence), person-to-person care (ren, usually rendered as “benevolence” or “humanity”) is the significant trait of being human. To be a caring person is to be a moral example or moral authority for others to follow. After proper rearing, a person needs instruction from a Confucian teacher to develop his or her practice of caring. This instruction focuses primarily on gaining literary achievement (wen); memorizing the Four Books (four ancient and venerated Confucian texts), large sections of the Five Classics (also important Confucian texts), and other important Confucian works; and learning Confucian rituals and music so as to habituate the student in the practice of being virtuous.

person who achieves the status of being a noble and moral example for others, that is, a prince of virtue.

Although Confucius had his gender biases, the content and practice of his moral teachings are similar to those of the feminists who advocate a contextual care ethic. Speaking generally, Confucius, like the feminists of care, was concerned about interpersonal relationships founded on love and affection; his known writings contain nothing of an ethics based on impersonal duty. In the writings of both Confucius and certain feminists, moral values are learned at home by participating in a morally healthy parent-child relationship. The writings of Confucius emphasized the father-son relationship rather than the feminist mother-child relationship, but both advance the importance of proper child rearing for the cultivation of a moral personality that learns to contextualize values and actions in particular situations in relation with particular persons.
The Confucian virtues are best understood in terms of actual human behavior rather than intellectual beliefs. Confucians, both past and present, are concerned with the practice of taking care of others, not the abstract idea of care. The five constant virtues are person-to-person care (ren), ritual action (li), rightness (yi), trustworthiness (xin), and moral wisdom (zhi). Person-to-person care is defined as “love” in the Analects of Confucius. Confucians do not advocate random acts of love; all of the virtues must be practiced according to the requirements of ritual action. Confucian society is based on ritual order, not legal order.

The art of contextualizing the virtues in practice is clearly expressed in being a person of rightness (yi). Although the examples of the ancient sages serve as a guide, no absolute standards of rightness exist. Rightness entails doing the right thing to the right people at the right time in the most appropriate manner. Confucius invested a lot in trustworthiness (xin); exemplars of the moral must stand by their words. They must practice before they teach others, and they must teach only what they themselves have practiced.

Even moral wisdom (zhi) should be understood in terms of practice, or doing the right thing, rather than merely knowing what should be done. It is bolstered by the virtues of literary accomplishment (wen) and studiousness (xue). Any virtue may have to be practiced with bravery (yong). The virtues of reverence (jing) and sincerity (cheng), only briefly mentioned by Confucius, were developed by later Confucians and were understood to be part of the structure of the universe.

Mencius and Later Philosophers
Whereas the writings attributed to Confucius were primarily concerned with the practice of moral behavior, those attributed to the Chinese philosopher Mencius (371–289 BCE) understood the cardinal virtues to constitute the operations of the human heart-mind. Although the writings of Mencius and Xunzi (c. 310–213? BCE) disagreed on the natural goodness of humans, with Mencius claiming that people are basically good and Xunzi that they are basically deviant, both emphasized the importance of proper rearing, education, and ritual action for the correct expression of moral virtues. Not until Zhou Dunyi (1017–1073) and Zhang Zai (1020–1077) revitalized the study of Confucianism did all the Confucian virtues come to take on a cosmological as well as a social moral role. To the extent that Korean, Japanese, Vietnamese, and other Southeast Asian cultures adopted and adapted Confucianism, they also accepted and transformed Confucian ethics to meet their social and moral needs.

Confucian Sites at Qufu
Qǚfǔ Sān Kǒng 曲阜三孔

The city of Qufu, Shandong Province, the legendary birthplace of Confucius, is the seat of the “Three Kongs:” The Temple and Cemetery of Confucius and the Confucian Family Mansion. The complex today is a major tourist site; it has been one of China’s foremost protected cultural relics since 1961 and a UNESCO World Cultural Heritage Site since 1994.

The Confucian Temple (Kongmiao 孔庙) and the Family Mansion (Kongfu 孔府) lie side by side in the southern part of the Qufu, Shandong Province, the birthplace of Confucius. The cemetery (Konglin 孔林, or Wooded Park of Confucius), lies about four kilometers to the north. Together they are known as “San Kong,” or “The Three Confucian Sites.”

The Temple

The Temple of Confucius was built onto the structure of Confucius’s three-room house to commemorate him in 478 BCE, a year after his death. In 153 BCE it officially became a temple of the state. During the course of history the temple has experienced four major destructive fires (with the first caused by lightning in 1499); it was rebuilt each time.

Today the temple complex measures about 650 meters from north to south and 150 meters from east to west, covering an area of about 95,000 square meters (about 24 acres). The complex contains nine courtyards comprising more than a hundred buildings that have a combined total of 466 rooms. A broad “sacred path” (shendao 神道), flanked by tall cypresses, runs through the middle of the temple. The famed Kuiwenge 奎文阁, a three-storied pavilion used as a library, stands in one of the courtyards. Walking further north, one sees fifty-three steles. They are among the temple’s five thousand stone tablets dating back to the dynasties of Song, Jin, Yuan, Ming, and Qing, (from 960 to 1912, inclusive) with epitaphs in scripts from different ethnic Chinese such as the Han, the Mongolian, and the Manchu. Some of the epitaphs are written in Phags-pa, a fabricated script with which Khubilai Khan meant to replace all other languages during the Yuan Dynasty (1279–1368).

The most important part of the temple lies farther north. It is divided into three sections. In the middle is the Dachengdian (“Palace of Great Accomplishment 大成殿”). Modeled after the structures of the Imperial Palace in Beijing, it was rebuilt in 1724 after it was destroyed by another fire caused by lightning. As one of its unique features, its roof is supported by twenty-eight marble columns, embellished with carved reliefs of dragons and clouds. The use of the dragon motif, a sole privilege of the monarch that was denied to common people, shows that the descendants of Confucius enjoyed royal status.

The original residence and altars of Confucius, as well as the first four generations of his descendants, are in the east section of the temple. Confucius’s parents are worshiped in the west section. The last of the nine courtyards houses the Palace of the Sage’s Deeds (Shengidian 圣迹殿) with carved stone portraits of Confucius and...
an additional 120 stone carvings from the Ming dynasty (1368–1644) depicting the political travels he made during his life time.

The Family Mansion

Adjoining the east section of the Temple of Confucius is his Family Mansion, also known as the Family Mansion of Duke Yansheng. (Yansheng, meaning “overflowing with wisdom,” was the honorary title that successive Chinese rulers and governments gave to the descendants of Confucius from 1055 to 1935.) The mansion was originally built for a fifty-fifth-generation descendant of Confucius by the Hongwu Emperor of Ming in 1377 and rebuilt by the Hongzhi Emperor in 1503. A decade later, the mansion was relocated to where it is today to be part of the “Three Kongs.”

The Family Mansion of Confucius occupies more than twelve acres, extending 352 meters from north to south. Its north end runs 111 meters long; and its south end, 193 meters. Like the Temple of Confucius, the mansion complex is also divided into three sections. Nine courtyards consisting of 480 rooms sprawl through the middle section. Stepping into the first few courtyards from the south, one finds rooms that used to serve as offices, where the Yansheng dukes performed their official duties. Further north, one enters the courtyards that functioned as living quarters. The courtyard in the far north was the family garden. The east section of the mansion includes official reception rooms, utility rooms, and an ancestral temple, and the west section was designated for private reading and social activities.

The mansion, renovated several times in history, houses a large collection of archives, costumes, artifacts, and crafts of great historical value, documenting the family’s affairs and activities from 1534 to 1948. Since 1949, research in the archives has yielded over nine thousand volumes of books.

The Cemetery

Four kilometers to the north of the Temple and Family Mansion of Confucius is located the Cemetery (Konglin,孔林), the largest and oldest of family cemeteries in China. A grey brick wall 7.3 kilometers long and over 3 meters high surrounds this 494-acre cemetery park, which has a number of different types of trees, many planted in the Song (96–1279) and Yuan (1279–1368) dynasties. From the memorial archway known as paifang in the very south that serves as the entrance, a sacred path over a kilometer long leads to a large castle-like structure named Guanlou.
A creek, dubbed Shengshui (Water of the Sage) flows from west to east across the cemetery. Across a bridge to the north is the Hall of Enjoyment (Xiangdian 享殿), where tribute is paid to Confucius through offerings of incense.

Behind the Hall of Enjoyment are the tombs of the Confucian Family, with Confucius himself in the center. On the left is the tomb of his son Kong Li. In the front is that of his grandson Kong Zisi. This peculiar layout is in conformity to a Chinese burial tradition, in which the father appears to be holding the son in one hand and carrying his grandson in the other.

In addition to the tombs of the three Confucian ancestors and their direct descendants, there are also tombs of famous people in and outside of the Confucian family. Kong Shangren (1648–1718), a famed playwright, is one of them. He is buried there because he used to show the Kangxi Emperor (1654–1722) around the cemetery. Direct descendants of Confucius have been buried in the cemetery for generation after generation, their tombs numbering more than a hundred thousand. Out of reverence and in respect for the Confucian ideal of moral strength, monarchs over the past two thousand years have renovated the Cemetery of Confucius as many as thirteen times. Today it has become not only a place for worship, but also a source for research in the burial customs from the Spring and Autumn period (770–476 BCE) to the Qing dynasty (1644–1912). With numerous trees of various species, the cemetery is also regarded as a botanical garden.

Confucian Temples

Kŏngmiào 孔庙

Confucian temples are places to worship Confucius, his students, and other Confucian thinkers. But they also served as arenas for Chinese rulers throughout history to express to their subjects the value of culture and education. Many of these temples in China, no longer active for worship, have become bastions of China’s complex culture. Qufu Temple, in Shandong Province, is the oldest and most iconic.

The teachings of Confucius have shaped Chinese thought and values throughout history; Confucian temples in China are primarily places to worship the philosopher and his disciples. But many Confucian temples today have become valuable repositories of Chinese culture in the form of museums and educational facilities. The Qufu 曲阜 Confucian temple in Shandong Province, for instance, is now the most popular tourist destination in China after the Forbidden City.

The History of Qufu

Confucian temples are located all over China, but the temple at Qufu, is the largest and best preserved. Qufu was built in 478 BCE, the year after the death of Confucius, on the site where Confucius’s house stood. The king of

Luguo 鲁国 (kingdom of Lu), Luaigong 鲁哀公, who had often asked Confucius for advice, was grief stricken he died. He ordered Confucius’s three-room house consecrated as a temple to store the great philosopher’s bequests, such as clothes, hats, musical instrument, and books. Thus the three sections became the embryonic form of the Confucian temple.

The original dwelling of Confucius was removed from the Qufu site when the temple was enlarged in the seventh century CE, and the temple was expanded again during the Song dynasty (960–1279) into three sections with some four hundred rooms. Fire and vandals destroyed Qufu in 1210. After more renovations and rebuilding—and nearly three hundred years—a lightning-sparked fire in 1499 destroyed the temple complex once again.

**“Imperial” Qufu**

Visitors to Qufu today are sure to remark on the how much the temple complex resembles the Forbidden City, and not surprisingly. Because the most dramatic transformation of Qufu was begun in the Ming dynasty (1368–1644) during the reign of Emperor Hongzhi (明孝宗, 1487–1505), shortly after the construction of the Forbidden City, the two sites share many features of imperial-style architecture and general configuration. The project took about five years to finish.

Hongzhi ordered that the Qufu temple be built in imitation of the Beijing imperial palace, and includes nine courtyards arranged symmetrically along the more than 1,000 meter-long central axis. The temple contains a pavilion, an altar, two wing rooms, two halls, three ancestral

Confucian Temples

halls, five palaces, seventeen kiosks with steles (carved or inscribed stone slabs or pillars used for commemorative purposes), and fifty-four memorial gateways. The temple has 104 buildings in all, consisting of 4,666 rooms, and covers 9.6 hectares.

Some of the rooms devoted to Confucius include: Dachengdian 大成殿 (Hall of Great Achievements), where a statue of Confucius is located; Shengjidian 圣迹殿 (Hall of Memories of the Sage), where Confucius’s life story is exhibited; and Qindian 寝殿 (Confucius’s Bedroom), where Confucius’s wife is worshiped. There is also a library named Kuiwenge 奎文阁, meaning “the best literary talent.”

Confucius’s famous students and other famous Confucian thinkers also have their place of honor in the two wing rooms standing to the east and west of the main palace. Although Confucian temples in other places are smaller than Qufu, they are similar in arrangement and pattern.

“Governmental” Temples

In 153 CE the Huandi 汉帝 emperor (132–168) of the Han dynasty 东朝 (206 BCE–220 CE) ordered an official to oversee the installation of a stone memorial inside the temple at Qufu and to designate it as a temple of the state; this was the beginning of the “governmental” Confucian temple. From then on the ruler of every dynasty always repaired a dilapidated temple after it was ruined by war.
or by natural calamity. Thus Confucian temples became destinations for emperors and imperial officials wanting to remind their subjects that moral development of the individual is crucial to the establishment of a state governed by moral rather than coercive laws.

In 539 CE statues of Confucius and his ten famous students were sculpted in the Qufu temple; this was the beginning of the tradition of setting statues in Confucian temples. Not long after the Tang dynasty (618–907 CE) was founded, Emperor Li Shimin ordered the building of a Confucian temple in every province and county of China. Temples were also constructed at Guozijian (national colleges), the highest educational institutions during China’s three final dynasties.

**Destruction and Decay**

Because of war and natural calamity, Confucian temples built before the Song dynasty no longer exist: Qufu was not the only “victim” of destruction and decay. Only those built during the Ming dynasty (1368–1644) and Qing dynasty (1644–1912) remain. and established the pattern of the Qufu Confucian temple today.

In 1724 the Qufu Confucian temple again burned again. The Emperor Yongzheng (雍正, 1722–1735) of the Qing dynasty ordered it rebuilt according to the established Ming pattern. The project took six years. The main architecture of the Qufu Confucian temple today is the legacy of that rebuilding.

At the beginning of the Cultural Revolution (1966–1977), in November 1966, as many as six thousand artifacts from Qufu were destroyed by two hundred students enlisted by the Red Guard. They also opened Confucius’s tomb, in the town north of Qufu in a cemetery where 100,000 descendants of Confucius are said to be buried, but found no human remains. In the 1980s public worship at Qufu was reinstated, and in 2004 the government organized an official worship ceremony at Qufu, the first since 1948. The Chinese Communist Party, in a gesture perceived to propagandize and expand awareness of traditional Chinese culture, organized an international day of worship centered at Qufu in 2005, with services held simultaneously all over China and in countries abroad; local Chinese officials who organized ceremonies and parades in their cities and town welcomed the additional tourist attention.

**Future Roles**

The temple at Qufu was designated in 1994 as a United Nations Educational, Scientific, and Cultural Organization (UNESCO) World Heritage Site, a status ensuring that the temple will remain a strong symbol of China’s past culture, a boon to its tourist industry, and, perhaps, in light of China’s new interest in reviving Confucian thought, a place to inspire a new generation of Chinese.

Confucianism

Rújiào 儒教

The teaching of the philosopher Confucius inspired philosophers and statesmen for more than twenty-five-hundred years. Confucianism stresses the importance of education for moral development of the individual so that the state can be governed by moral virtue rather than coercive laws.

Confucianism is a system of thought based on the teachings of the philosopher Confucius (or Kong Fuzi [Grand Master Kong], 551–479 BCE). Confucianism includes the complete literature, teachings, and practices of the traditions that are aligned with Confucius. Han dynasty (206 BCE–220 CE) bibliographers classified the works of Confucius and his disciples under the heading “literati.”

Syncretism

Scholars often claim that traditional China was a Confucian society or that before the twentieth century Confucianism was the official state religion and philosophy of China. Such claims are overgeneralizations and misleading. First, the syncretic (relating to the combination of different forms of belief or practice) nature of both early and late Confucian thought must be understood. Second, the hybrid syncretic character of later state-sanctioned Confucianism must be understood.

Speaking generally, the cultures, philosophies, and religions of East Asia are syncretic in nature. Because of their practical orientation, they do not place great value on exclusive ideas or practices but instead prefer to absorb and integrate whatever proves to be useful. This practice is particularly true of Chinese culture and philosophy and is in large part the reason why the dynastic system was effective and enduring.

Their syncretic, amalgamated character and content are what have made the teachings of Confucius so attractive to so many thinkers for more than twenty-five hundred years. Confucius, his contemporary followers, and most of his later followers incorporated various forms of literature. They emphasized poetry, legend, history, divination, music, and ritual. They integrated virtue and self-cultivation with the notions of harmony and a political philosophy. The Confucian curriculum was well rounded. It consisted of the six arts: ritual, music, archery, calligraphy, chariot driving, and mathematics. Confucius also stressed that any serious student, even a commoner, should be trained in military arts. Confucians assumed that the masses would be engaged in agriculture and related industry and incorporated agricultural skills into their social program, although they did not place great stress on these skills because they were more concerned with moral cultivation.

Borrowing from statesmen who were concerned about properly naming job titles and evaluating job performances, Confucius and others, especially the philosophers Mencius (385–303/302 BCE) and Xunzi (c. 300–230 BCE), delineated the meaning of the “rectification or attunement of names” (zhengming). This delineation was important because knowing the precise name
for one’s position in the world (as father, son, prince, and so on) let one know one’s responsibilities.

Confucians were at odds with a school of philosophy called the “Legalists” (fajia), who advocated a rigorous notion of the rule of law, as opposed to the Confucians’ notion of rule by virtue. Although Confucius, Xunzi, and Mencius believed that people should be ruled with virtue by setting a moral example, they also certainly recognized the need for law. According to tradition, when Confucius was chief of police, even he had to authorize the execution of a criminal. Confucians, like Legalists, sought to standardize a code of human conduct. Legalists sought to achieve this standardization by instituting public law, whereas Confucians sought to achieve it by placing greater emphasis on instituting a homogeneous system of ethics to govern human interactions, holding the law in reserve for cases of flagrant behavior.

Confucius clearly did not create a pure philosophical system; he borrowed from various approaches. Likewise, his followers absorbed elements from other schools of philosophy to bolster their interpretation of Confucius.

**Xunzi and Mencius**

Mencius is known for advancing the teachings of Confucius. However, whereas Confucius was concerned with the details of proper moral behavior, Mencius advocated a more abstract philosophy, emphasizing the goodness of human nature (xing) and the development of the mind (xin). Although Mencius had syncretic tendencies, he also criticized other philosophers, including the early Daoist Yang Zhu (c. late fourth century BCE); Mozi (479–438 BCE), the founder of Mohism, a philosophy that emphasized universal love; and Xu Xing (c. late fourth century BCE), who argued that a ruler should labor in the fields alongside his subjects. (Mencius answered Xu Xing by saying that the ruler should concentrate on ruling and leave farming to the farmer).

Xunzi a century later revitalized Confucian teachings by invigorating them with practical political measures such as economic means to enrich the state and a greater stress on public law. Xunzi is known for criticizing Mencius’s belief that human nature is basically good. Xunzi argued that people are basically selfish, given limited resources, but that people can be trained to be good through the practice of ritual action and education. Xunzi’s teachings dominated Confucian thinking from the Han dynasty to the Song dynasty (960–1279). During the Song dynasty Mencius’s teachings were used to develop neo-Confucianism.

**State-Sponsored Confucianism and Syncretism**

The syncretic approach to philosophy and the arts of rulership became particularly popular toward the end of the Warring States period (475–221 BCE) and the first part of the Han dynasty (the so-called Western Han, 206 BCE–8 CE).

Han emperors struggled with the problem of systematizing political philosophy and the arts of rulership. During the reign of the Han emperor Wu (156–87 BCE) Dong Zhongshu (c. 179–104 BCE) developed a composite form of Confucianism that became the state-sanctioned philosophy. Dong was a Confucian in that he praised Confucius and generally subscribed to the Confucian ideas of rule by virtue and self-cultivation. However, Dong integrated aspects of the Five Phases philosophy (a philosophy of the mystical composition of the universe out of five forces), Legalism, and Daoism into Confucianism.

The intellectual life of Confucianism stagnated after the Han dynasty. During the Tang dynasty (618–907 CE) Han Yu (768–824 CE) revived Confucianism with his study of the moral way (daoxue). He rejected Xunzi and emphasized the basic goodness of human nature.

**Zhou Dunyi, Zhu Xi, and the Cheng Brothers**

During the Song dynasty a Tang dynasty Daoist alchemical document called the “Diagram of the Great Ultimate” (Taijitu) was transmitted to the philosopher Zhou Dunyi (1017–1073). (The term alchemical relates to alchemy, a medieval science aiming to transmute base metals into gold, discover a universal cure for disease, and discover a means of indefinitely prolonging life.) Zhou wrote a profound work based on that document in which he linked the moral nature of humans with the nature of the universe and claimed that the goodness of human nature is part of the moral goodness of the universe.
Zhou Dunyi taught the Cheng brothers. Cheng Hao (1032–1085) and his younger brother Cheng Yi (1033–1107) developed Zhuo’s concept of a universal principle (li) that is inherent in all things, making it the foundation of their respective philosophies and the main concept of Song dynasty neo-Confucianism. They taught that the proper subjects for study are principle (li) and human nature (xing) and that human nature ultimately is identical to principle. For them the investigation of things was crucial for self-cultivation. They claimed that goodness is the life-giving principle of the universe.

The Cheng brothers influenced the neo-Confucian scholar Zhu Xi (1130–1200), who systematized the teachings of the Cheng brothers and Zhou Dunyi and argued that reality consists of two components: principle (li) and material force (qi). Principle is the form of everything that exists, whereas material force fills and activates things. Zhu taught that human nature is basically good because it is endowed with the principle (li) that is goodness. People learn to be bad, and thus the purpose of education is to retain the good principle in one’s original nature and to remove acquired pollutants. Zhu Xi sided with the rationalistic (relating to reliance on reason as the basis for establishment of religious truth) tendencies in Cheng Yi’s philosophy, and for several hundred years what is called the “Cheng-Zhu school of neo-Confucianism” dominated China.

Zhu Xi debated with Lu Xiangshan (1139–1193), who supported the idealistic tendencies of Cheng Hao’s philosophy. Lu focused on the mind, teaching that it is one with principle. For Lu the investigation of things meant the study of the mind. He argued for the unity of the Way (dao), opposing the distinction that Zhu made between principle and material force.

Ming and Qing Dynasties

During the Ming dynasty (1368–1644) Wang Yangming (1472–1529) developed the idealism of Lu Xiangshan. (In philosophy idealism means that reality is in the mind or in the ideas of the mind; it does not denote a perfect [ideal] world). Wang was a champion of the School of Mind (xinxue), as opposed to Zhu’s School of Principle (lixue). Wang argued that anyone can become a sage because everyone has a mind that contains innate knowledge of the good. This innate knowledge of the good extends outward, starting with a natural love for self and family, extending to community, and then outward to all other people, creatures, and things. Wang is known for teaching that knowledge and action form a unity. His philosophy influenced later thinkers such as Tan Sitong (1865–1898) and Sun Yat-sen (1866–1925).

In 1644 the Manchus conquered China and established the Qing dynasty (1644–1912). Under foreign occupation Chinese government officials were marginalized. To avoid criticism or punishment by the Manchus, many turned to scholarship and the study of
Confucian philosophy. Kang Youwei (1858–1927) and Dai Zhen (1724–1777) are two important Confucians of the Qing dynasty. Dai Zhen devoted his life to studying the Mencius (a book of Mencius’s conversations with kings of his time). Dai Zhen rejected the Chang-Zhu school and taught that human morality had its origin in blood-and-material force and the knowing mind. He taught that principle exists only when the feelings are not mistaken. Kang Youwei accepted a basic tenant of the Lu-Wang school that taught that book learning must be complemented with profound action. Kang was a scholar who advocated political and social reform. He saw Confucius as an innovative institutional reformer and proposed that Confucius was a divine being or god and the founder of a great religion. Kang adapted Dong Zhongshu’s concept of the three, suggesting that human history begins with an Age of Disorder, followed by an Age of Small Peace, culminating in an Age of Great Peace. During the Age of Great Peace everyone and everything will be treated exactly the same; there will be one world order, one humanity, one great unity (datong).

Twentieth Century

Confucian scholars in the twentieth century revived the tradition with what is now known as “New Confucianism.” Feng Youlan (1895–1990) revitalized rationalistic neo-Confucianism and argued that everything in existence is undergoing a continuous process of realizing principle (li) by means of material force (qi). He taught that people live in one of four spheres of life: the innocent sphere, the utilitarian or practical sphere, the moral sphere, and the transcendent sphere. Philosophy helps people to live in the last two higher spheres of life: the moral sphere and the transcendent sphere. Feng’s notion of the transcendent realm was influenced by Daoist mysticism. Xiong Shili (1883–1968) reconstructed idealistic
Confucianism and advocated that reality is change, a perpetual process of production and reproduction or closing and opening. By “closing” Xiong meant that reality has the tendency to integrate, to momentarily be what we call “matter.” By “opening” Xiong meant that reality has the tendency to maintain its own nature, to be its own master, to momentarily be what we call “mind.”

When Chinese Communist Party leader Mao Zedong (1893–1976) and his followers won the civil war in 1949, Confucius and Confucianism were strongly attacked. Xiong, Feng, and all other scholars were forced to denounce Confucius and their own decadent views. However, after Mao’s death the Communist Party became far more tolerant of Confucianism such that by the 1990s party propaganda began to quote the ideas of Confucius or his followers.

New Confucianism has continued to develop as some scholars in China offer interpretations of the Confucian classics to help people cope with a rapidly changing China. Others are developing what Daniel A. Bell (2008), a scholar who teaches at Beijing’s Tsinghua University, has called “Left Confucianism,” which attempts to revitalize the intellectuals’ role as political and social critic. Some of the New Confucians are seeking to blend the humanitarian ideals of Marxism with those of Confucianism. In addition, in both Taiwan and the West, Confucianists advocate promoting Confucian values in democratic and capitalist societies.

Further Reading
As twenty-first-century China adjusts to changes brought about by the country’s opening to the West, Chinese are beginning to search for new and inspirational models, both in politics and as a philosophy to guide everyday life. Sinologists have been surprised that government officials, critical intellectuals, and ordinary citizens are turning not to Western liberal democracy for the answer, but to the venerable tradition of Confucianism.

In the late 1980s Chinese culture was viewed as the source of China’s “backwardness” and an impediment to modernity. Today, however, Chinese students often seek inspiration and guidance from Chinese culture, both for engaging in everyday ethics and for thinking about political reform. In this revival of Chinese culture Confucianism stands at the vanguard.

Several reasons exist for the revival of tradition in China. China is a rising economic power, and with economic might comes cultural pride. The view of the German political economist Max Weber, that Confucianism is not conducive to economic development, has come to be widely questioned in light of the economic success of East Asian countries with a Confucian heritage. Unlike Islam, Hinduism, and Buddhism, Confucianism has never had an organized resistance to economic modernization. It’s China’s turn to affirm its cultural heritage.

But modernity also has a downside: It often leads to a kind of atomism (individualism) and psychological anxiety. The competition for social status and material resources becomes more and more fierce, with declining social responsibility and other-regarding outlooks. Communitarian ways of life and civility break down. Even those who make it to the top ask, “What now?” Making money, people realize, doesn’t necessarily lead to well-being. It is only a means to the good life, but what exactly is the good life? Is it just about fighting for one’s interests?

Most people—in China, at least—do not want to be viewed as individualistic. The idea of simply focusing on individual well-being seems too self-centered. To really feel good about ourselves, we also need to be good to others. Here’s where Confucianism comes in: The tradition is based on the assumption that the good life lies in social relationships. To be fully human involves an ethic of social responsibility and political commitment. In short, Confucian ethics can help fill the moral vacuum that often accompanies modernization.

Of course, a more political reason underpins the revival. Communism has lost its capacity to inspire the Chinese: Hardly anybody believes that Marxism should provide guidelines for thinking about China’s political future. The ideology has been so discredited by its misuses that it has lost almost all legitimacy in society. In reality even the “Communist” government won’t be confined by Marxist theory if it conflicts with the imperatives to remain in power and to provide stability and harmony in society.
Why Confucianism?

Not surprisingly, perhaps, the government is turning to tradition rather than Western-style liberal democracy as a new source of political legitimacy. Government leaders are quoting Confucius and deploying Confucian values such as harmony and civility in their speeches. Political practices also reflect such values: Chinese Communist Party officials in Henan Province are assessed on the basis of Confucian values such as filial piety and family responsibility. The 2008 Beijing Olympics highlighted Confucian themes: A choir at the opening ceremony chanted well-known sayings from the Analects of Confucius, and booklets handed out to visiting journalists were sprinkled with such quotes as well. Abroad the government has been promoting Confucianism via branches of the Confucius Institute, a Chinese language and culture center similar to France’s Alliance Française and Germany’s Goethe Institute.

But the revival of Confucianism is not just government sponsored. Many critical intellectuals are also turning to Confucianism to think of ways of dealing with China’s current social and political predicament. For most of the twentieth century both Chinese Marxists and liberals engaged in a comprehensive critique of their own heritage and looked to the West for inspiration. Today many Chinese intellectuals also look to their own traditions for thinking about social and political reform. Without entirely rejecting Westernization, they believe that stable and legitimate political arrangements need to be founded, at least partly, on political ideals from their own traditions. Such ideals as meritocracy, civility, and social harmony are being revived and promoted, not just by the government but also by independent intellectuals and students.

Over the last decade or so the teaching of the Confucian classics has moved back into the mainstream of society. Once dismissed as “feudal,” “hierarchical,” “patriarchal,” and “backward,” the Confucian tradition is being examined more charitably, with lessons being drawn for present-day society. An explosion has taken place in conferences and books on Confucianism in China. Courses on Confucianism are among the most popular on university campuses. The teaching curriculum for secondary schools now includes teaching of the classics, and many experimental schools focus largely on the classics. More than 10 million children are now studying the Confucian classics, many through ad hoc initiatives outside the formal educational system.

Diverse Traditions

In short, this mixture of psychological, economic, political, and philosophical trends helps to explain the revival of Confucianism in China. But Confucianism is a rich and diverse tradition, and more than one type of Confucianism is being revived. The most influential intellectual involved in the revival of Confucianism is Yu Dan, who has written a self-help book on the Analects of Confucius that has sold over 10 million copies (including 6 million pirated copies). She is a national star who often appears on television to lecture about the benefits of Confucianism for everyday life. Yu Dan also visits Chinese prisons and lectures prisoners about Confucian values. From an academic point of view, however, her contribution may not be as significant: She deliberately avoids controversial themes and resorts to ahistorical simplifications to make her points. More problematic, Yu Dan herself is openly committed to a relatively individualistic form of Daoism, and her interpretation of Confucianism neglects key Confucian themes such as social responsibility and political commitment. Her account of the Analects seems apolitical, but it deflects attention from the economic and political conditions that actually cause people’s misery. It is an implicit justification for the status quo.

The more academic revival includes historical studies and interpretations of key figures in the Confucian tradition that are not meant to have direct bearing on contemporary society. Of greater interest for our purposes are the competing interpretations of political Confucianism: interpretations that are meant to affect the way we carry out our social and political lives. Perhaps the most influential form—the form disparaged by twentieth-century critics—is traditional “conservative” or “official” Confucianism. Throughout Chinese imperial history Confucianism was combined with Legalism, China’s other main political tradition, to justify such practices as blind obedience to the ruler, the use of harsh punishments as a tool of social control, and the subordination of women in ways that offend modern sensibilities.
Today the Chinese government emphasizes “harmony” and family values such as “filial piety.” Such values may still be worth promoting—if harmony means the peaceful resolution of social conflicts instead of violent Maoist class revolution, who can object to that?—but they are often used in problematic ways that justify social quietude and submission to the powers-that-be. To be fair, the official promotion of Confucian values has been an improvement compared with the past: Today, few government officials openly invoke Confucian values to justify the subordination of women (and some academics like Chan Sin-yee are reinterpreting Confucianism so that its central values, like the idea that we should all strive to become exemplary persons, do not exclude women). Still, there is a need to consider the more critical interpretations of Confucianism.

One such interpretation is “liberal Confucianism,” promoted largely by scholars outside of China such as Tu Weiming and Theodore de Bary. According to “liberal Confucians,” Confucianism need not conflict with liberal values such as human rights and democracy and can be used to promote those values. But that’s also the problem with “liberal Confucianism”: Liberalism is used as the moral standpoint to evaluate Confucianism. The parts of Confucianism that are consistent with liberalism should be promoted, and the parts that conflict should be rejected. But this sort of approach doesn’t take Confucianism seriously as a tradition that can enrich and challenge the liberal tradition. Is it not possible that Confucianism can offer a compelling alternative to Western liberalism?

Left Confucianism is an attempt to combine the socialist tradition with the Confucian tradition—and in a way that doesn’t just take socialism as the standard but takes Confucianism equally seriously, such that Confucianism enriches and changes socialism during the course of the encounter. But one should address—parallel to the concern that leftists are using the Confucian label simply to promote progressive or socialist ideas that owe their origin to Western roots—a concern that would parallel a critique of “liberal Confucianism.” Granted, such “Western” values as social democracy, solidarity, human rights, and the rule of law need to be adopted in China. But they also need to be adapted in China. They need to be enriched, and sometimes constrained, by Confucian values. The meaning of “left Confucianism” will become more clear by sketching some traditional leftist values and showing how they might incorporate some “Confucian” characteristics. Not each characteristic is distinctly Confucian, but together they may constitute a distinctive package that warrants the label left Confucianism.

Independent Social and Political Criticism

The ancient Greek philosopher Socrates was famous for truth-seeking, and he was merciless in exposing the errors of those who made false claims to the truth. The Socratic model still informs the educational system in Western countries, where students are taught the importance of
developing a critical perspective on what they learn and seeking the truth without worrying about social harmony. The critical perspective also informs Confucianism. One of the most famous lines of the *Analects* of Confucius—that exemplary persons should pursue harmony but not conformity—has clear political implications. The contrast between harmony and conformity owes its origin to the *Zuo Zhuan*, which clearly referred to the idea that the ruler should be open to different political views among his advisers. In imperial Chinese history the ideal of the independent social critic was institutionalized in the institution of the Censorate, consisting of scholar-officials who had the mandate to criticize the government’s mistaken policies. Independent Confucian academies, often located far from the country’s capital so as not to be subject to political control, trained scholars in the art of criticism. Confucian-inspired social critics such as Yang Jisheng and Huang Zongxi penned more radical political criticisms outside of formal channels. Today social critics have drawn on the contrast between harmony and conformity to urge the government to be tolerant of differences and not simply enforce one dominant state ideology on the whole population.

But a Confucian twist, so to speak, is that criticism is best carried out on the basis of social harmony and trust. If two enemies criticize each other, they will question each other’s motives, and the result may be more bad blood. Criticism may be most effective—in the sense that it leads to improvement—if it’s founded on affective ties. Whether in the family or in the political realm, criticisms should be seen as being motivated by affection rather than hostility. In practice, it means that criticisms should be expressed in gentle and humble ways, so as to maintain harmonious relationships. Today the language of “not losing face” is used to express this ideal. The strident and self-righteous criticisms of some Western politicians and Western-based human rights organizations often fall on deaf ears in China because they are viewed as rude and
disrespectful even by those who might agree with the substance of the criticisms. Conversely, the cooperative and long-term-minded approach of such organizations as the Danish Institute of Human Rights is often more effective.

Today, of course, the media are often regarded as an important vehicle for public criticism, with investigative journalists aiming to expose official wrongdoing and social injustices. Left Confucians favor more space for an independent media with the power to tell the truth about social problems and blame the government when it’s at fault. From a Confucian perspective, however, there is also cause to worry about the kind of media model that focuses almost exclusively on bad news. It is fine to encourage private media to report on news as they see fit (so long as they avoid extreme violence and pornography), but an important task of the media would also be to promote social harmony. Such media reporting might involve the portrayal of moral exemplars, appeals to people’s better nature, and sympathy for the disadvantaged. More concretely, a Confucian-inspired model of media regulation might mean space for private media but also funding for public media that seek to promote social harmony rather than loyalty to the party. The publicly funded media might well involve positive portrayal of government leaders when they contribute to social harmony—the television news showing President Hu Jintao singing along with disabled children during the Paralympics was an inspiring moment—because leaders who do good should be seen as setting examples for others. But it is equally important for leaders who do bad to be subject to criticism.

Concern for the Disadvantaged

Socialists and left Confucians can agree that the government’s first obligation is to provide for the disadvantaged in society. To a certain extent they can also agree about what it means to be disadvantaged: It means being deprived of material goods that underpin any decent conception of the good life. But the Confucian would add that being disadvantaged is not just about lacking money. An equally serious harm is being deprived of family members and friends who make up the good life. Hence, when Mencius says the government should give first consideration to “old men without wives, old women without husbands, old people without children, and young children without fathers,” he doesn’t mean just that people are materially poor. For Mencius they are disadvantaged (partly, if not mainly) because they are deprived of key human relations. Such views help to explain why East Asian states with a Confucian heritage often rely on the family to provide welfare services, with the state stepping in to help those without family members. For example, health care insurance in Singapore is family rather than individual based—with family members responsible for each other’s insurance, including the obligation of adult children to take out insurance for elderly parents—and

People pass by beggars on the street in China on their way to temple. PHOTO BY ROBERT EATON.
similar arrangements have also been implemented in China’s rural areas. The state takes responsibility for elderly parents without relatives. Such insurance schemes might seem peculiar in Western countries, but they are not nearly as controversial in East Asian countries with a Confucian heritage.

**Concern for Economic Equality**

Socialists seek to reduce the gap between rich and poor. In Western countries they also tend to favor social equality, that is, a society in which people treat each other as equals regardless of status. To the extent possible, the elderly and the young as well as bosses and assistants should disregard social status when they engage in everyday social behavior: For example, they should address each other on a first-name basis. There may be several reasons why social equality and economic equality are thought to go together. One reason is that an ideal society would do away with all power relationships, whether based on social status or class (modern liberal ideas put forth by some philosophers, such as John Rawls’s original position and Jurgen Habermas’s ideal speech situation, are meant to express the ideal of equal power). Another reason is that social equality is more likely to contribute to economic equality: The more likely people treat each other as social equals, the more likely they are to support measures that reduce the gap between rich and poor.

Confucians do not deny that an ideal society should do away with all power relationships. But such utopian ideals may be appropriate only for small communities of like-minded people, such as Israeli kibbutzim, or advanced technological societies where machines would do almost all of the unwanted labor, as in Marx’s ideal of communism. Confucians are realists in the sense that they take for granted that power relationships will exist in large-scale societies and that the question is how to make those power relationships work for the interests of the powerless. And here’s another Confucian characteristic: Confucians worry less about social hierarchies, particularly hierarchies based on age and achievement. If a choice must be made between social equality and economic equality, then Confucians would choose economic equality, and social inequalities should be made to work for economic equality.

How might that work? The ancient Confucian thinker Xunzi proposed the idea of social rituals that include people of different social statuses. By participating in common rituals, those with more status come to develop feelings of care for the others and thus become more willing to do things in their economic interest. For example, a boss in Japan or South Korea might enjoy singing karaoke with a worker. The ritual is hierarchical—the boss sings first and perhaps for a longer period, but after a period of singing and drinking affective bonds are strengthened, and the boss is less likely to dismiss the worker in difficult economic times. Such rituals help to explain the practice of lifelong employment in large Japanese and Korean corporations. More generally, such inclusive rituals help to explain why Japan and Korea—perhaps the most socially hierarchical societies in East Asia—also have relatively equal distributions of wealth.

A small society such as that of Norway, which is relatively homogeneous and endowed with substantial natural resources, may be able to afford equality all the way through. The Confucian, however, recognizes that the choice for most societies is between a socially egalitarian society like the United States, where the way to express power typically takes the form of wealth, and societies governed by informal rituals that express differences in social status, in which the powerful do not have to rely to the same extent on material wealth to show their “superiority.” For the Confucian the latter society is preferable: The key is to promote rituals involving the powerful and the powerless so that the rich are made to feel a sense of community with the powerless and thus are less likely to seek other forms of domination (such as material wealth).

Another difference between Western socialists and Confucians is that the former are more likely to favor political and civil rights over economic rights (in cases where such rights conflict) as a society seeks to secure material equality. The U.S. Constitution expresses the basic liberal preference for civil and political rights. Even left liberals such as John Rawls stipulate without much argument that civil and political rights outrank principles of economic justice in cases where they conflict. Rawls does allow for very poor societies on the verge of starvation to prioritize the right to food, but that’s about as far
as most leftists in the West are prepared to go in terms of sacrificing civil and political rights in the interests of economic rights.

In East Asia it’s not just the Chinese Communist Party that believes the right to food comes first. The idea that the state has an obligation to deal with material deprivation goes back more than two thousand years—as opposed to Western political history, where poverty was considered a problem for political stability or a matter for charity until the eighteenth century or so. Hence, it shouldn’t be surprising that the obligation to secure a people’s means of subsistence is a widely held value that trumps other political values in cases of conflict. China is probably beyond the “Rawlsian minimum,” meaning that few Chinese are starving or malnourished, and yet the idea that democracy should wait until the economy is more developed is not nearly as controversial as it might be in leftist circles in the West (whether there actually is a conflict between democratic rights and economic development now in China is an empirical question, but where the issues are not so clear cut even independent leftist Chinese intellectuals might prefer not to argue forcefully for democracy now). Another example might be the hukou (household registration) system in China, which limits people’s mobility in the interests of securing a stable and orderly environment for economic development. The hukou system is breaking down now, but there are still restrictions on moving to large cities such as Shanghai and Beijing, and such restrictions are not nearly as controversial as they might be in the West.

**Solidarity with Strangers**

The value of solidarity is central to the socialist tradition (and less central to the liberal tradition). In the West socialists have argued for realizing solidarity by different means. For French revolutionaries the task was to change the political system as well as hierarchical social practices, such as banning the use of the formal personal pronoun vous in favor of the informal tu. For Marxists the path to solidarity lies in violent class revolution that would abolish private ownership of the means of production. Social democrats argue for realizing the value of solidarity by means of a state-enforced system of equal rights for all citizens.

The Confucian way to solidarity is different in both means and ends. The idea is expressed in the opening passage of the Great Learning:

> The extension of knowledge consists in the investigation of things. When things are investigated, knowledge is extended; when knowledge is extended, the will is sincere; when the will is sincere, the mind is rectified; when the mind is rectified, the personal life is cultivated; when the personal life is cultivated, the family will be regulated; when the family is regulated, the state will be in order; and when the state is in order, there is peace throughout the world. (Tian Xia)

The idea is that ties should be extended to others, starting from the family to the state and ultimately to the whole world. But the end is not a universal solidarity by which all treat each other as equals. Rather, ties are extended with diminishing intensity, so that strangers will be treated well but without the same degree of love shared among family members.

And how is this ideal of “graded love” to be realized? Confucians have emphasized two mechanisms. The first is to learn care and compassion within the family and then to extend care to others by applying family-like labels and norms to nonfamily members. In Chinese, for example, students and alumni will refer to each other as younger or older siblings; graduate supervisors will refer to their students as younger siblings; and (in the best cases) employers and employees will use family-like language to refer to each other. The extension of such terms of family endearment to nonfamily members is far more widespread than in most Western languages and contributes to a sense of solidarity in East Asian societies.

Confucian solidarity is also realized by means of rituals that civilize and elevate, particularly in the context of competitive relationships that would otherwise degenerate into hostility and antagonism, if not warfare. Confucians take for granted that human desires can undermine social cooperation, but the task is to civilize those desires rather than suppress them. And it’s particularly important for the “winners”—those with power and social status—to act in civilized ways, to show modesty and courtesy during the course of rituals designed to civilize human desires. These rituals are particularly evident in sporting activities, past and present. Confucius’s account of the
gentleman-archer—“Exemplary persons are not competitive, but they must still compete in archery. Greeting and making way for each other, the archers ascend the hall, and returning they drink a salute. Even during competition, they are exemplary persons” (3.7)—echoes the rituals of sumo wrestlers. Such rituals also inform sports that developed in Western countries—the rituals of helping opponents up after a fall and exchanging sweat-soaked shirts at the end of football games come to mind—but they are more central to sporting traditions that developed in Confucian-influenced East Asian societies. In the 2008 Beijing Olympics the gold medal winners from China often seemed humble and kind to opponents, perhaps due (at least partly) to the civility campaigns conducted prior to the games. In the same vein the Chinese fans were generally respectful of other teams and athletes.

Global Justice

Socialists often take a global perspective on justice. Confucians agree—the ultimate end of politics is a form of government that serves the whole world’s peoples, or at least takes their interests into account: a politics for the people. But which people count? Leftists in the West tend to emphasize the interests of the current generation of the world’s peoples and more recently, in response to the environmental movement, the interests of future generations. But Confucians also take seriously the interests

Rubbings from residence of descendents of Confucius. Qufu, Shandong Province. The Chinese government in the twenty-first century is turning to tradition rather than Western-style liberal democracy as a new source of political legitimacy, quoting Confucius and deploying Confucian values such as harmony and civility in their speeches.

of their dead ancestors. In Confucian-influenced South Korea and southern Chinese provinces such as Fujian, for example, many households and communities still practice ancestor worship. The Confucian scholar Jiang Qing has proposed a house of government (the House of Historical Continuity) with the explicit task of maintaining continuity of various traditions, including the traditions of minority groups such as Tibetan Buddhists. For Confucians, identities are constituted by the values and practices of one’s ancestors, who may still be hovering overhead in some form or other, and it doesn’t seem so far-fetched to think about how to secure the interests of one’s not-so-dead ancestors in social and political life. Put differently, a regime that secures the interests of the current generation of the world’s peoples but neglects those of its descendants and ancestors would be unjust from the perspective of left Confucians.

Another key difference lies in ways of thinking of how to realize politics for the people. Perhaps the most sacred political value in the West is politics by the people in the form of “one person, one vote.” Those who question this democratic mechanism are often thought to have lost their moral bearings. (In the nineteenth century, it was a different story: The British philosopher John Stuart Mill justified democratic mechanisms in terms of their consequences, and he was prepared to contemplate modifications that produce better consequences.)

One clear problem with “one person, one vote” is that equality ends at the boundaries of the political community; those outside the community are neglected. The national focus of the democratically elected political leaders is part of the system, so to speak; they are meant to serve the community of voters, not foreigners living outside the political community. Even democracies that work well tend to focus on the interests of citizens and neglect the interests of foreigners. But political leaders, especially leaders of big countries such as China, make decisions that affect the rest of the world (consider global warming), and they need to consider the interests of the rest of the world when they make decisions.

Hence, left Confucians put forward political models that are meant to work better than Western-style democracy in terms of realizing global justice. The ideal is not necessarily a world where all persons treat each other as an equal—as mentioned, Confucians favor extending care but recognize that care will diminish in intensity as it extends from intimates to strangers—but rather one where the interests of strangers would be taken more seriously than in most nation-centered democracies. And the key value for realizing global justice is meritocracy, meaning equality of opportunity in education and government, with positions of leadership being distributed to the most virtuous and qualified members of the community. The idea here is that everybody has the potential to become morally exemplary, but in real life the capacity to make competent and morally justifiable political judgments varies between people, and an important task of the political system is to identify those with above-average capacity. One idea might be to give extra votes to elderly people. Confucians assume that wisdom normally increases with age as people’s roles change and life experience deepens—the role of an adult child caring for an elderly parent in particular cultivates such virtues as empathy and humility—and as they gather longer experience in particular roles. A doctor with a few years’ experience, for instance, should have better understanding and judgment than a brand new doctor.

Another proposal is for a meritocratic house of government, with deputies selected by such mechanisms as free and fair competitive examinations, which would have the task of securing the interests typically neglected by democratically selected political decision makers such as foreigners, future generations, ancestors, and minority groups. A meritocratic house of government would balance and complement a democratic house, and, however imperfect, the idea is to better approximate the ideal of global justice. The value of political meritocracy is deeply embedded in East Asian political discourse, and political proposals to realize it are not typically seen as eccentric or dangerous (in the West, by contrast, much of the political discourse assumes that states must be either democratic or authoritarian, and alternatives that do not fit neatly within that dichotomy are often dismissed out of hand).

Another characteristic of left Confucianism is support for humanitarian intervention abroad, but only if the aim is to remove tyrants who violate people’s right to life. Even Mencius, the most “soft” of the left Confucians, defended the idea that wars can be launched abroad in order to remove ruthless tyrants who are resistant to morality. Leftists in the West who defend humanitarian intervention have abroad put forward different justifications. For Michael Walzer, perhaps the most influential theorist of
just war, the value of membership in a particular political community is a fundamental human good and helps to underpin judgments regarding the justice of warfare. Other prominent intellectuals such as Michael Ignatieff and Thomas Friedman defended the U.S. invasion of Iraq partly on the grounds that it was supposed to promote democracy in the Middle East. Left Confucians reject both those justifications for humanitarian intervention: Only the relief of human suffering at the hands of a tyrant could justify the use of armed force abroad.

Religious Toleration

Today most leftists recognize the ideal of tolerating different forms of religions. The “fact of pluralism” is a feature of modern societies, and it seems only fair to allow different people to practice the forms of religious life that are most compelling to them. Even those who are convinced of atheism do not argue for banning religion. But some leftists in the West object to any role for religion in public life.

Left Confucians do not take a strong view regarding religion. Following the example of the early Confucian thinkers such as Confucius himself, they leave open metaphysical commitments, focusing their efforts on the problems of earthly life. Hence, it’s not inconceivable to be a Confucian in social and political life and, say, a Buddhist or Christian regarding metaphysical commitments. Early Confucianism was not meant to provide a final answer to existential questions about human suffering and life after death, and it leaves open the idea that religions may do a better job in that respect.

But some left Confucians like Jiang Qing do take Confucianism seriously as a religion with a metaphysical foundation and draw the implication that there should be official state sponsorship of Confucianism as a kind of religion. The idea is that Confucianism needs to be taught in schools and promoted in villages and communities with some sort of financial support from the state. Partly the idea is to train future rulers in Confucian ethics so that they will rule with moral sensitivity. But Jiang Qing emphasizes that other religions would be tolerated, and he compares his ideal with state support for official religions in Sweden and the United Kingdom: Other religions would not be prohibited and would be able to flourish despite state support for one religion. Jiang explicitly makes room for the political representation of other religions in his proposed third house of government, the House of Historical Continuity.

Still, the idea of state support for Confucianism does seem to go well beyond the northern European model, especially in terms of state backing for Confucianism in education and community life. Jiang Qing has also proposed the reintroduction of state-supported Confucian burial rituals after natural disasters such as the 2008 Sichuan earthquake (although he allows for the possibility that members of minority groups could follow their own burial rituals). Another way in which “official Confucianism” would influence policy is that civil servants would be able to take paid leave for a limited period of mourning in the event of the death of a parent, similar to the one-month period of mourning leave granted to civil servants in South Korea. It could also be argued that Confucian ideas already influence state policy—for example, elderly parents are entitled to a share of property if an adult child dies intestate in the People’s Republic of China, Hong Kong, and Taiwan, notwithstanding different political and legal systems—and making Confucianism official would make such policies matters of public debate and perhaps lead to improvements. If such proposals for “official Confucianism” are implemented in ways that tolerate and respect other religious practices, they are worth taking seriously. The history of “official Confucianism” in imperial China does offer reason to be wary of state misuses of Confucianism, but it also offers some inspiring moments. In the late sixteenth century, as Yu Ying-shih notes, Matteo Ricci was amazed to discover that the Chinese religious atmosphere was highly tolerant, with Confucianism, Buddhism, and Daoism all seen as capturing a vision of the same Dao (Day).

Beyond China?

Early Confucian thinkers assumed that their ideals were universally valid: They were meant to be applicable to all human beings, and an ideal world would be composed of people who endorse (and live by) those ideals. A world where different people live in accordance with different values in different parts of the world would have been considered second best. In that sense Confucianism
is put forward as a philosophy with universal validity, similar to liberalism and Christianity. It is inaccurate to say that liberalism is universal whereas Confucianism is particularistic: They are both meant to be universal in scope.

But which interpretation of Confucianism makes most sense in China today depends on particular factors. It depends on what Chinese people actually think now: Any interpretation must be consistent with basic aspirations, though it should also push to improve those aspirations. For example, left Confucianism may be compelling to Chinese because it draws and builds on widely shared values such as concern for the disadvantaged. It also depends on what Chinese intellectuals regard as pressing needs. Jiang Qing, for one, thinks there is a need for a different philosophical foundation for the state. He argues that Marxism no longer appeals to people and that Confucianism is most likely to do so. Hence, he tries to articulate an interpretation of Confucianism that addresses the political need for institutions that are stable in the long term because they are founded partly, if not mainly, on Chinese political traditions. Interpretations of Confucianism also depend upon claims that can be supported by empirical evidence. It would be important, for instance, to test the idea that caring for elderly parents is an important mechanism for developing a sense of empathy extended to others.

Under what conditions is Confucianism likely to be seen as compelling by the rest of the world? One condition is that societies undergo prolonged crises of confidence. It is a sad truth, perhaps, that people are more inclined to learn from others when their own ways prove to be problematic. Chinese intellectuals looked to the West only when traditional ways of social and political life broke down, and it may take a similar crisis of confidence in the West before large numbers of Western intellectuals turn to Confucianism for hope and inspiration. Meanwhile it is important for the West to tolerate, if not respect, areas of morally justifiable areas of difference. Another condition that would aid the project of universalizing Confucianism is that Confucian ideas are widely seen as influencing China's political practices and institutions. The theory has to come alive, so to speak. After the Chinese state acts morally in accordance with Confucian ideas, then it can articulate and promote its soft power to the rest of the world. If it's just talk, nobody will listen.

The philosopher Confucius, China’s greatest teacher, stressed such values as moral integrity and empathy and such practices as rule by virtue rather than by law. His teachings continue to influence Chinese and other Asian cultures.

Confucius is recognized as China’s greatest teacher. His family name was “Kong,” and his personal name was “Qiu” (stylized as “Zhongni”), but he was eventually given the title “Kong the grand master” (Kong Fuzi), which has been Latinized as “Confucius.” He was born in the state of Lu (in Shandong Province) in 551 BCE during the Zhou dynasty (1045–256 BCE). Confucius’s father died when the son was three; by seventeen, Confucius supported his mother. Confucius married at age nineteen, had two daughters and a son, and held a minor office in Lu. He dedicated his life to teaching but believed that he was called to reform the decaying Zhou culture.

At the age of fifty-one Confucius was promoted to magistrate and subsequently to the post of minister of justice. Discouraged by conditions in Lu, when he was fifty-six Confucius and his closest disciples traveled to other states to find a worthy ruler to implement Confucius’s teachings. However, after almost thirteen years Confucius returned to Lu to teach. Tradition says that he wrote or edited the Five Classics (Shujing, Shijing, I Ching [Yijing], Chunqiu, and Liji) and the now-lost classic of Music. Of the three thousand students he is said to have had, only seventy-two mastered his teachings, and only twenty-two were close disciples.

After his death Confucius’s reputation underwent a process of apotheosis (elevation to divine status). By
the time of the philosopher Mencius (371–289 BCE), Confucius was called a sage. During the Han dynasty (206 BCE–220 CE) emperors often made offerings at his tomb, which became a shrine and later a temple. Confucius was given the imperial title “duke” in 1 CE, “foremost teacher” six hundred years later, in 637, “king” in 739, and “perfect sage” in 1013. By 1906, two and a half millennia after his birth, the ritual for the “emperor on high” was performed in the name of Kong Fuzi.

During the Song dynasty (960–1279) the scholar Zhu Xi streamlined Confucian education by compiling the Four Books: Mencius, Analects, Great Learning, and Centrality and Commonality; the Analects is usually considered most important. With typical “Chinese humility,” Confucius claims in the Analects to be a transmitter rather than an innovator. This claim is certainly not the case, but it displays the importance of maintaining historical precedent, namely, following the example of the ancient sages to practice self-cultivation, to sacrifice personal wealth and needs for the good of the community, and to rule by virtue rather than by law.

Confucius indeed was an innovative teacher. He opened his school to all serious students, even commoners, transforming aristocratic values into collective moral values. His teaching methods went beyond vocational training, emphasizing moral cultivation, which institutionalized the literati class and influenced Chinese history.

Confucius stressed literacy (wen) and required that his students be enthusiastic, serious, and self-reflective. His teachings are practical. He taught that all persons, but especially members of the ruling class, must develop their moral integrity by practicing ritual action (li) to express person-to-person care or humanity (ren) to become a consummate person (junzi). Empathy (shu), defined in the Analects as “never do to another what you do not desire,” summarizes his teachings in a single word. With the renewed interest in Confucius, even in the People’s Republic of China, his teachings continue to influence Chinese and other Asian cultures.

The Confucius Institute is a nonprofit public organization established in 2004 and run by China’s Office of Chinese Language Council International (Hanban) under the Ministry of Education. Its mission is to promote Chinese language and culture throughout the world.

The Chinese government initiated the Confucius Institute in response to the growing interest in China and the international demand for Chinese language instruction. In this way, it is similar to the U.K.’s British Council and Germany’s Goethe Institute.

After establishing a pilot institute in Tashkent, Uzbekistan, in June 2004, the first Confucius Institute opened in November 2004 in Seoul, Korea. Today they are found on every continent (except Antarctica); by 2009, there were 307 Confucius Institutes in seventy-eight countries. The most recent opening was at the University of Costa Rica in November of 2008. The Confucius Institutes often have been formed within existing universities and colleges, although according to the official website this is not a prerequisite. Some are also found in public education settings. Regardless of location, they abide by local laws and regulations and are subject to supervision and inspections from the local educational administrative authorities.

The Ministry of Education estimates that by 2010 there will be approximately 100 million people worldwide learning Chinese as a foreign language; it plans to set up more than one hundred additional Confucius Institutes worldwide, according to Xu Lin, director of the Chinese Language Council International (‘China threat’ countered by culture 2006). The Internet will be used in the future as well: Michigan State University’s Confucius Institute has established a Chinese education island in Second Life, the online “virtual meeting environment.”

Public and institutional reactions to the Confucius Institute vary. There is concern about their sponsorship by the Chinese government, with fears that this could lead to undue influence from Beijing on curricula within Asian studies departments of colleges and universities where the institutes are located. On the other hand, they are being widely adopted throughout the world with the hope of teaching the world about China and ultimately fostering mutual collaboration.

Consumerism in China is not a new development; for hundreds of years Chinese have used material goods to convey status and identity. Mass consumerism, however, is a relatively new phenomenon that has both advantages and disadvantages to the social and economic fabric of China.

The development of modern mass consumerism in China and subsequent transformation of most aspects of life has been both beneficial and detrimental to the Chinese. Hundreds of millions of people have been lifted from poverty and have the opportunity to enjoy products and services previously unavailable or unaffordable. In the past few decades, China has become the world’s largest consumer of a number of products, including everything from meat to mobile phones. The lives of tens and even hundreds of millions of consumers in urban China increasingly resemble their American, Japanese, and European counterparts. At the same time, China’s rapid increase in per capita consumption threatens its and the world’s environment.

Chinese elites have used luxury goods as a way to create identity and communicate status for hundreds of years. As late as 1800, the wealthiest part of China in the lower Yangzi Valley surrounding Shanghai may have been as wealthy as the richest part of Western Europe. And local elite circles created social capital by exchanging rare gifts, assembling expensive dowries, collecting art objects, and hosting lavish weddings and funerals. Textiles, teas, opium, books, and other commodities were consumed well beyond the regions where they were produced. Consumption habits gradually spread down the social hierarchy and luxuries such as sugar and tea became more widely consumed.

But “modern consumerism,” which refers to the consumption of branded, mass-produced goods and services, and the orientation of social life and rhetoric around consumption, is a more recent phenomenon. The bleak material conditions in China from World War II through the civil war (1945–1949), and throughout the Maoist era (1949–1976) misleadingly suggest that modern Chinese consumerism arrived only after the death of Mao and Maoism. But China has had elements of modern consumerism since the late nineteenth and early twentieth century. Urban China, particularly the key treaty ports of Guangzhou, Tianjin, and particularly Shanghai, encouraged consumerism through modern retailing, exhibition halls, and advertising. Varying modes of transportation, such as rickshaws, automobiles, and bicycles, established more integrated markets, and new public environments within modern schools and workplaces were used to showcase new products. In addition, urban China supplied the energy sources necessary for the electricity required by new consumer products and lifestyles. During this time, Chinese people, especially but not exclusively urban elites, introduced new objects into their homes and leisure activities. And a growing number of Chinese altered their appearance from head (Western-style hats) to toe (leather shoes and cotton socks).

Understanding the impact of these commodities is challenging, particularly with regard to how people used
and thought about all the products and services they consumed. Unlike Americans and western Europeans, Chinese did not leave detailed probate records revealing exactly what households owned, but the memoirs of foreign travelers readily show that Chinese adapted imports for local and even individual purposes. For instance, fashionable urban women in the early twentieth-century confidently mixed and matched traditional and imported clothing articles to invent their own original styles. This adaptation also was common for Chinese citizens least likely to have access to information about or contact with foreigners and how they used their material artifacts. Often the Chinese weren’t encumbered by the knowledge of a product’s intended use. Urban slum dwellers, for example, built shacks out of discarded iron Standard Oil cans.

Despite these consumptive behaviors, Chinese consumers were not always free to consume whatever they could afford, nor could they determine the social significance of the items they bought. In China, modern consumerism has always been connected with imperialism. During the nineteenth century, Europeans, Americans, and eventually the Japanese demanded access to Chinese markets. Through the First Opium War (1839–1842) the British and subsequently many others achieved access to Chinese markets at a time when the relative superiority of Chinese material culture had declined markedly. That is, the products of the industrializing imperialist powers were appealing, and the Chinese learned to desire imports. In the nineteenth century, the most prominent of these imports were opium and Western military hardware, but by 1900 the desire for imports extended to a vast array of consumer goods, including silk, considered to be the symbolic heart of China. Japanese silk displaced Chinese silk in foreign markets and increasingly penetrated the domestic market. From concepts of male and female beauty, to forms of sport and entertainment, to styles of architecture and personal appearance, Chinese associated the foreign and Western with a better and more fashionable lifestyle.

During the first half of the twentieth century, the rapid increase in imports and the desires they stimulated threatened powerful domestic interest groups. Chinese politicians worried about trade deficits and the new consumer lifestyles. Educated elites, who had begun to read works on Western political economy, feared the loss of sovereignty implicit in the growing foreign dominance of the economy, and manufacturers struggled to produce products to compete against new imports. These concerns ultimately produced a multifaceted “Buy Chinese” campaign.
conducted in cities across the country. Advocates developed countless ways to exhort fellow Chinese to consume China-made goods, including skillfully co-opting foreign commodity spectacles like product exhibitions. Also, as the outbreak of frequent anti-imperialist boycotts demonstrates, they forced consumers to buy Chinese. Nevertheless, in the absence of a powerful state to enforce the nationalistic consumption of Chinese products through tariffs, such efforts had limited success.

The establishment of the People’s Republic of China in 1949 soon ended the ease with which consumers embraced consumerism for four reasons: Mao Zedong’s well-known anti-urban biases, the initial decision to emulate the Soviet Union’s economic model with its emphasis on state-owned heavy industry and neglect of consumer goods, the elimination of private enterprise, and the appeal of autarkic (self-sufficient) economic growth after a century of imperialism. The Communists gradually forced foreign multinationals to leave China and eliminated most foreign brands from the marketplace by imposing higher tariffs and outright bans. After some initial hesitation, which allowed consumer lifestyles to persist into the mid-1950s, the state appropriated all private enterprises, eliminating the trend-setting consumer class of urban capitalists.

“Consumerism” is not usually associated with Mao’s China because China under Mao radically reshaped consumerism; however Mao’s influence never eliminated consumerism fully from Chinese life. China continued to mass-produce a limited number of branded goods, and consumer goods and services remained objects of everyday discussion and important building blocks for personal and collective identity. The Communists worked tirelessly to eliminate all traces of consumerism, particularly following the shift to ideological over material incentives during the Great Leap Forward (1958–1960) and the Cultural Revolution (1966–1976), but even the most extreme attempts to eliminate consumerism may have had unintended consequence of heightening a form of consumer consciousness.

The spread of consumerism in East Asia after World War II culminated in China. In 1978, Deng Xiaoping began depoliticizing daily life and launched economic reforms that led to growth rates equal to Japan’s earlier record levels. Now the Chinese state stakes its political legitimacy on economic growth and encourages citizens to consume, a shift in attitudes and policies toward consumerism embodied in the popular Communist Party slogan of the 1980s: “To get rich is glorious!”

The market reforms of the late 1970s and 1980s...
introduced tremendous uncertainty for consumers. Fixed prices shifted to market prices, creating new consumer issues, including resentment of unfair pricing, the sales of imitations through deceptive packaging, food adulteration, false advertising claims, product liability, and warranty issues. Chinese consumerism was fraught with media scandals and popular panics and rumors surrounding products and services. For instance, in the summer of 1985, a scandal erupted over the sale of supposedly dirty imported used clothing that was sold as new. Furthermore, a Beijing textile and clothing association report concluded that the clothing was not just used but came from people with diseases. That winter at least twenty cities and counties participated in efforts to find and destroy the offending clothing.

This unstable environment led to a “consumer movement” that included academic, bureaucratic, and social dimensions. In 1983, the Chinese government sponsored the creation of the Chinese Consumers’ Association, the country’s central consumer protection association. By 2001, the association had 3,000-plus local branches across China and had received over 6 million consumer complaints. The 1980s also saw the beginnings of the academic study of consumerism and the publication of consumer magazines and newspapers to protect “consumer rights,” as they became known. Finally, the Chinese Communist Party recast itself as a protector of consumers. The party-state established regulatory agencies such as the National Administration of Industry and Commerce, which regulates trademarks and advertisements, and the Commodity Inspection Bureau, which requires companies to add product warnings.

For over a decade but especially after the global financial crisis of 2008, Chinese and world political and business leaders have pinned their hopes for domestic and global economic growth on Chinese consumers. In other words, Chinese must save less and consume more. In 2008, rising political star Vice Premier Li Keqiang voiced the conventional wisdom among top policy makers, “Boosting domestic demand is essential for proping up growth,” (China’s vice premier urges demand boost: state media, 2008) especially in the face of global economic weakness. Chinese leaders have implemented policies designed to address the anxieties behind high savings, which include escalating medical, education, housing, and retirement costs. To counter rising costs of living, Chinese leaders have permitted the establishment of private lending companies, accelerated urbanization, and instituted extended holidays around the lunar New Year, National Day (1 October), and, until 2007, Labor Day.
Day (1 May). They have also deregulated the financial sector to facilitate consumer borrowing through mortgages, credit cards, and car loans.

While some politicians and scholars anxiously wonder whether Chinese will consume enough, others speculate the opposite. The rise of Chinese consumerism with its reliance on a rapidly escalating use of non-renewable resources has created urgent questions about the sustainability of modern consumerism in China and elsewhere. The scale and scope of environmental problems directly related to the production of consumer goods for China and for the world cannot be overstated. Acid rain already falls on a third of the country, three to six hundred million Chinese lack access to clean drinking water and, with sixteen of the world’s twenty most polluted cities, a third of all urban residents breathe polluted air, prematurely killing over 400,000 people a year from asthma, emphysema, and lung cancer. What will happen as Chinese consumers, further urged by their government and the world, to “catch up” with the global North in per capita consumption of energy and other goods and services? Likewise, what’s the responsibility and culpability of the rest of the world for creating this dire situation?

Corporate Social Responsibility
Qiyè shèhùi zèrèn 企业社会责任

The history of corporate social responsibility (CSR) in China has as many variations as it has definitions. Understanding those definitions is key to realizing the varied ways that companies and consumers have interacted in the past and how they will do so in the future.

Corporate social responsibility (CSR) has gained a critical mass of attention in China in the last half decade. ChinaCSR.com, an online publication started in 2003, reports on a wide variety of CSR programs, conferences, and publications in China for both Western and Chinese companies. But many researchers point either to China’s opening up in the late 1970s or even to the Communist revolution of 1949 as the start of China’s commitment to connecting the ascendancy of industry with the social good. For the former viewpoint, China’s reforms in the 1980s and 1990s created an environment where businesses were held to higher standards and made to comply with new laws. As for the latter rationale that CSR has its roots in the founding of the People’s Republic of China in 1949, the creation of the danwei (work unit) was key to harmoniously placing the interests of the people in direct relation with how they produced goods, how they were cared for, and how they were schooled.

Even though these are simplified histories of the genesis of China’s CSR movement, they parallel the disparate ways that companies—and consumers—have come to think of CSR in China. While CSR is generally considered the overarching moniker used for connecting business with its impact on society, other terms like sustainability, corporate citizenship, and green company are frequently used. Under these vague terms comes a layer of more definitive words, such as cleantech, green building, supplier compliance, volunteerism, product safety, and charitable giving. Understanding that these words can mean both everything and nothing is crucial in determining whether a company is engaging in truly responsible behavior or is merely conducting a “greenwashing” campaign in China under the auspices of its misguided public relations firm.

Current Perspectives on CSR

While perhaps there was some fearful hesitancy a few years ago within the Chinese government to fully embrace a more updated idea of CSR, such as additional costs to exports, the situation has now changed. Not only are there new proposed regulations that would require foreign companies to submit their own sustainability reports within China, but various sectors within the Chinese economy have embraced both domestic and international standards to help propel Chinese businesses to greater heights around the world.

There has been a push recently to influence Chinese companies to comply with the international SA8000 standard for ethical workplace conditions, and in 2005, agencies in China worked with the European Union to formulate the China Social Compliance standard (CSC9000T) for the textile industry. On the heels of a tainted medicine scandal in 2007, a massive push was
initiated to provide a transparent mechanism within which Chinese pharmaceutical companies could operate, and at the same time, the Chinese advertising industry was provided better guidelines to give consumers more trustworthy corporate propaganda from these same drug companies. Individuals are empowered too: Chinese media is filled with daily reports of consumers suing companies because of corporate irresponsibility.

These varying initiatives underlie exactly how companies both define their CSR and undertake to make themselves more responsible to their stakeholders. A key difference between a company operating in China and one operating in Europe or North America is the hierarchy in which those companies place their respective stakeholders. Whereas a British company might focus on its customers and investors as its most vital constituencies, the government sits at the top of the CSR pyramid in China as the important stakeholder in a business. And partitioned further, a software company’s primary CSR focus might be education, while a clothing manufacturer might be concerned more with worker safety. Just as every snowflake is slightly different, there is no one way to formulate CSR initiatives across the business spectrum. Any attempt at defining what is and what is not CSR usually comes from the lips of paid “sustainability consultants” who thrive on confusing corporate executives with hollow caveats and hyperbole.

According to ChinaCSR.com, the American chamber of commerce in Shanghai gives awards annually for CSR; a review of award recipients shows the diversity of its projects. In 2008, the award went to FedEx and Orbis for their work in promoting education about and training for the treatment of preventable blindness in China. The overall CSR award for small and medium businesses went to PMI Shanghai International Trading for its efforts in compliance, audit, and environmental initiatives. In addition, a sustainable community development honor was given to acknowledge the partnership between electronics manufacturer Tecsun and Changjiang Civilian Education Foundation.

**Outlooks for CSR**

While it’s important to understand some of the various ideas of how and when CSR developed in China, it is critical to understand where CSR is heading in the future. With Chinese firms like Haier, Lenovo, and Chery making advances into foreign countries, companies who were once reticent about embracing CSR as a business fundamental are now faced with a global supply chain that can easily cause havoc everywhere in the world if one small link is broken. Companies are proactively reaching out to engage government, consumers, investors, and suppliers in multifaceted initiatives to bolster legal compliance, create better brand equity, strengthen financial oversight, and ensure sound manufacturing principles. One employee in China working in a food processing factory who does not wash his hands can infect food shipped around the world and affect the company’s brand over a long period of time. And the Internet now ships bad news around the world faster than companies can react.

Faced with both the opportunity of grabbing new market share around the world and the risk that irresponsibility can impair that growth, Chinese companies are flocking to undertake CSR programs. The United Nations Global Compact and the Global Reporting Initiative have gained steam within China in recent years with more adherents, and more companies are creating CSR director and CSR manager roles. Hong Kong-based hotel chain Shangri-La recently unveiled a new sustainability manager position, and the Shanghai Pudong Development Bank has a team who work together on enhancing the bank’s CSR functions.

But some worry that the current financial troubles could impact this trend. ChinaCSR.com speculates that as goes the global economic downturn, so goes funding for corporate expenditures deemed nonessential, including some CSR programs. Many are put on hold until an institution regains financial footing, and in China, CSR program managers are worried about losing traction for their initiatives in China.

The biggest CSR hurdles for Chinese companies will continue to be the same problems that plague their Western counterparts. First, as Chinese companies grow they will have more suppliers around the world. Each supplier is a potential weak point, and so continual oversight is necessary. Next, every company runs the risk of greenwashing. After the Sichuan earthquake in 2008, some Chinese companies were ridiculed for not only giving too little in donations, but also for making the act of donating too much of a public relations gimmick. Finally, full
commitment from a company’s executive management and board of directors is intrinsic to encouraging corporate social responsibility to be deeply ingrained in all the business processes. Even during recessions, companies must focus on the long-term benefits of CSR.

Corruption

Tānwǔ fǔbài 贪污腐败

Corruption has always plagued China, even as it has been frowned on by most of society. Factors embedded in the modern, Communist, system—such as centralization of the economy, state control of resources, lack of a clear division between public and private sectors, and a single political party—seem to promote corruption.

Tanwu, the Chinese word for corruption, comprises characters literally meaning “dirt” and “greed.” When combined with the word fūhuá or fūbài, the meaning is “a corrupt individual, society, or government.” The Chinese people generally regard corruption as a serious social and political problem. Leaders of the Chinese Communist Party (CCP) have realized that the practice has gravely threatened its legitimacy and have repeatedly launched anticorruption campaigns.

Corruption in China has a long history. The writer-philosophers of the early classical documents regarded corruption as a moral depravity, a violation of the prevailing moral code. Even the emperor was accountable. An emperor who was corrupt had betrayed his Mandate of Heaven, which gave him his right to rule. As early as the Qin dynasty (221–206 BCE), punishment was meted out for public corruption. The Qin criminal code contained a list of severe penalties for offenses related to “dereliction of duty in office.”

Public corruption contributed to the Taiping rebellion (taiping tiengo, “the Heavenly Kingdom of Great Peace”) of 1851 to 1864, the largest uprising in modern Chinese history. Government mismanagement of public works and a weakening economy, along with military defeats at the hands of Western forces, sparked the rebellion. Leaders of this pivotal event in Chinese history introduced many of the ideas and reforms that helped shape modern China.

In the People’s Republic, the definition of corruption has changed according to the political aims of the period. In more politically radical times, deviation from the prevailing ideology, which was considered antisocialist or bureaucratic behavior, was a sign of corruption. During these times reports of corrupt behavior were seldom made public. Only at the end of the 1970s, as reform policies began to emerge, was the press permitted to report cases of corruption again.

Some cases of corruption became public spectacle. This was the time of the trials of the infamous “Gang of Four,” four officials of the CCP accused of attempting to seize power after Mao’s death. The gang—led by Jiang Qing, Mao’s last wife—and their associates were branded as counterrevolutionary forces and officially held accountable for most of the turmoil of the Cultural Revolution.

Despite periodic crackdowns on public corruption, the problem continues. Factors embedded in the system—such as centralization of the economy, state control of resources, lack of a clear division between public and private sectors, and a single political party—seem to promote corruption. Psychological factors, too—such as defects in the revolutionary model, changes in values, shortages of goods and resources, and the division between town and country—contribute to corruption.
To make matters worse, recent reforms such as decentralization, opening to the outside world, a growing market economy, migration, and changes in property structures have led to increases in corruption in some areas. Without reforms that lead to a redistribution of power, officials within and outside of the party continue to control resources and freely line their own pockets.

COSCO Group
Zhōngguó Yuǎnyáng Yùnshū Gōngsī
中国远洋运输公司

China Ocean Shipping Group Company (COSCO) is one of the world’s largest shipping companies, and the major vehicle supporting China’s manufacturing export economy. COSCO is also one of the largest state-owned enterprises, owned by the central government of the People’s Republic of China, and in recent years has formed many joint ventures with foreign governments and companies.

On 27 April 1961 in Beijing, the China Ocean Shipping (Group) Company (COSCO) was formed from a collection of state-owned shipping enterprises (SOE 国有企业), including the Chinese-Polish Joint-Stock Shipping Company, itself founded in 1950 as one of the first Sino-foreign joint-owned enterprises. During the next two decades COSCO established international liner and container liner services to Europe, Asia, and eventually the United States, reestablishing past transportation and ownership ties to non-Communist countries and reintroducing direct transportation between China and the United States in 1979.

Now known as the “COSCO Group,” the company continued expanding in the 1990s, attracting minority-ownership shares through public listings on the Shanghai and Shenzhen stock exchanges and the Singapore exchange in 2004 and the Hong Kong exchange in 2005. COSCO Group currently comprises more than three hundred subsidiaries operating in all aspects of the shipping and transportation industry, including supporting research and financial services, with a reported combined value of $17 billion in 2008. The company is also a pioneer in supporting oceanographic and shipping research, including an expedition to Antarctica in 2005 and the construction of large semisubmerged container vessels. The group, China’s largest shipping company, operates a fleet of more than six hundred ships, with a shipping capacity of 35 million deadweight tons (DWT), plying trade to more than 1,300 ports in 160 countries and employing 80,000 people, including 5,000 non-Chinese. As with all of the nearly two hundred state-owned enterprises directly owned by the central government of the People’s Republic of China, its officers and directors are appointed by the Central Committee of the Chinese Communist Party. In recent years COSCO leaders have served as delegates to the National Party Congresses and the governmental National People’s Congress.

In bulk shipping COSCO has some two hundred vessels with total carrying capacity of 12 million DWT. In tanker shipping COSCO has eighteen tankers capable of shipping 1.8 million DWT, and among these are five of the “very large crude carriers” class (VLCC), each capable of holding more than 300,000 DWT. The group owns 1,200 land vehicles, 231 barges capable of carrying 187,000 DWT, 2.65 million square meters of stock yards, and warehouse space totaling 250,000 square meters. The group claims to be the eighth-largest container terminal operator in the world, with thirty-four berths around the world with a total annual throughput of 13 million containers. COSCO is a major shareholder in other Chinese state-owned enterprises, including those in ship repair,
ship building, container construction, international finance, second-hand ship sales, and marine bunker construction and operation.

COSCO has often been the target of investigations by foreign governments and shipping industry associations that have accused it of unfair trade practices, including support in the form of subsidized credit and resources from the Chinese government. Nevertheless, foreign governments and corporations have formed many joint ventures with the shipping giant. COSCO estimates that it regularly conducts business with more than five thousand business enterprises globally. The nature of COSCO Group’s relationship with the Chinese government is not clear, however, because its internal ownership and management relationships are, as with many Chinese state-owned enterprise groups, famously unclear.

Courtyard Houses (Siheyuan)
With at least one courtyard enclosed by four single-story buildings that face inward toward the open space, siheyuan represent the quintessential Chinese “courtyard houses.” Throughout China quadrangular courtyard structures come in many configurations, including many that are multistoried and others that have mere “skywells” with shafts of open space instead of broad courtyards. But siheyuan are best known because of their ubiquity in Beijing and other northern cities.

Classic siheyuan associated with Beijing and neighboring cities, where they are found in many configurations, are sometimes quite simple but more often rather complex in terms of layout. Virtually all siheyuan share canonical elements: enclosure behind high gray walls that afford substantial seclusion; a single off-center entry gate that controls access; orientation to the cardinal directions, with main structures facing south or southeast to ensure maximum sunlight and passive solar heating during winter; balanced side-to-side symmetry that represents a balanced aesthetic; and an organization of space along a clear axis that is associated with family hierarchy. Sumptuary regulations during the Ming dynasty (1368–1644) and Qing dynasty (1644–1912), which were nonetheless often flouted, were supposed to regulate the overall scale of siheyuan dwellings by controlling the dimensions of timbers and thus the width of halls, the nature of entryways, and colors and other ornamentation. As a result, the siheyuan residences of nobles and imperial princes were generally clearly differentiated from those of merchants, who had the resources to build large siheyuan but were constrained by regulations from doing so, and the more modest structures of common people.

Early in the Qing dynasty scores of sprawling siheyuan mansions of imperial princes existed in Beijing, the configurations of which were consistent with the codified sumptuary regulations appropriate to twelve princely ranks. For the most part, except for elements of the entry way, princely mansions could not be distinguished from ordinary siheyuan dwellings from the outside. But inside they replicated to some degree the facilities found in the Forbidden City, reduced, of course, in overall dimensions. Princess Der Ling, first lady-in-waiting to the Empress Dowager Cixi (1835–1908), wrote that “The houses in Peking are built in a very rambling fashion, covering a large amount of ground, and our former house was no exception to the rule. It had sixteen small houses, one stor- ey high, containing about 175 rooms, arranged in quadrangles facing the courtyard, which went to make up the whole; and so placed, that without having to actually go out of doors, you could go from one to the other by verandas built along the front and enclosed in glass” (Der Ling 1911). Manor-type siheyuan of this type became essentially extinct by the middle of the twentieth century: Some deteriorated, others were renovated to become the headquarters of institutions or multi-family dwellings for the poor, and many were demolished to facilitate the building of modern structures and roads. In the hutong lanes (narrow alleyways) surrounding the Shichahai and
Beihai lakes, remnants of some of these manors survive but mostly only in vestigial form.

The only site that is easily visited is just to the north of the Imperial City walls, where elements of the siheyuan manor of Prince Gong, the brother of the eighth Qing emperor Xianfeng, (reigned 1851–1861), the father of China’s last emperor, Puyi, still stand. The gardens of Gong Wang Fu, the palace of Prince Gong, were opened to the public in the late 1980s, displaying impressive rockeries and pavilions. Yet the sprawling old residence itself remained hidden, its manifold alterations and scars resulting from having been used after 1921 to house Furen Catholic University, then Beijing Normal University and the Chinese Music Academy, and finally the Beijing Air-Conditioning Factory during the tumultuous Cultural Revolution (1966–1976). On the eve of the Olympics in 2008, the expansive mansion was reopened to the public.

**Typical Layout**

The layout of a relatively conventional siheyuan with its series of gates, open spaces, and independent structures can be seen in the siheyuan on Huguosi hutong, once the residence of Mei Lanfang, one of China’s preeminent Beijing Opera singers. A single entryway with a pair of large doors painted red along the southeast portion of the outer wall leads to a small vestibule with a light gray brick spirit wall, a partition that visually separates the outside from the inside. Turning left leads through another gate into

---

**Courtyard in a Garden in Shanghai, 1979.** Virtually all courtyards share similar elements: enclosure behind high gray walls that offer substantial seclusion; a single off-center entry gate that controls access; and an orientation to the cardinal directions, with main structures facing south or southeast to ensure maximum sunlight and passive solar heating during winter. **Photo by Joan Lebold Cohen.**
a “public” zone, a narrow rectangular open area used by servants, by visitors waiting to be announced, and by a busy household to store bicycles, briquettes for cooking, and other items. Two large deciduous parasol trees spread their branches over the narrow courtyard. On the south side of the courtyard, in which are planted two large shade trees, is a north-facing building called a daozuō, or “rear-facing” structure. Facing the daozuō is a “festooned gate,” or chuihuamen, that leads to the inner central courtyard, although the view is blocked by a patterned screen wall.

Together the large inner courtyard and the rectangular one at the entry and another slender one on the west side of the residence make up more than 40 percent of the total ground area of this siheyuan. The interior courtyard, with trees and potted shrubs, serves as the center of family life. Tables and chairs from adjacent rooms can be moved into the courtyard for family members and their guests to enjoy sunny days and quiet evenings.

As with any classical siheyuan, the main hall, called a zhengtang, is a low, south-facing, single-story building on the northern side of the courtyard. Within this building the senior generation resides, with space for entertaining guests and family. Bedrooms and studies are also found here. Perpendicular to the main structure is a pair of flanking buildings, one facing east and the other west, normally used to house married sons and their families.

An important element of Beijing siheyuan is the set of narrow covered verandas that serve as all-weather passageways around the courtyards. Because the surrounding individual buildings are structurally separate, each side of
the quadrangle is entered and exited through a door facing the focal courtyard. Since no doorways interconnect any of the adjacent buildings that make up the courtyard complex, movement between buildings is most direct across the courtyard during fine weather.

Decline and Fall

Throughout Beijing after 1949 courtyard houses increasingly came to be shared by many unrelated families rather than continuing to be private dwellings for extended families. Once-commodious spaces were divided up, and courtyards filled in as “temporary” kitchens, bedrooms, and storage sheds. In time the essential organic core of many siheyuan, the courtyard itself, was obliterated by structures. Limits on running water, toilets, drainage, and maintenance in general led to the deterioration of the once-proud structures.

In 1990 authorities began demolition of siheyuan and hutong neighborhoods in general to facilitate the modernization of the city by eliminating substandard housing and rebuilding residential quarters to meet current needs. Quickly many residents raised alarms about the demolition of the city’s architectural patrimony. Residents of many ramshackle siheyuan dubbed them zayuan or “mixed-up courtyards” because of the dilapidated condition they were in and the fact that they were occupied by many households. Efforts by government authorities to conserve individual structures and neighborhoods have been slow and uneven. Private efforts have had some effect. After two decades of sweeping destruction of hutong neighborhoods, less than a thousand siheyuan have been designated for preservation. Even courtyards that seem “safe” because they are listed for preservation have sometimes been summarily demolished to the dismay of residents and preservationists.

China only recently has embraced the modern creative economy. China realizes that to become less dependent on others and to increase domestic consumption, it must create its own value-added goods and services and produce its own brands to sell, not only in China but also worldwide.

One of the most basic trends in the global economy is the growth in economic value attributed to the creative imagination—to art, design, entertainment, and culture in their widest sense. China, by concentrating its growth plans from 1970 to 2000 on manufacturing low-cost exports to foreign specifications, was late to take part in that trend. But the government increasingly realized that in order to become less dependent on others and to increase domestic consumption, it had to create its own value-added goods and services, exploiting Chinese brands and styles. China sees the creative economy as the premium end of manufacturing and services, adding more value than conventional businesses. China is acutely aware of the strength of brands such as Disney, McDonald’s, and Nokia and wants to produce its own Chinese varieties and sell them not only in China but also worldwide. The global economic crisis that started in 2008, and the consequent fall in export demand, gave the new policy added urgency.

The modern creative economy emerged in the United States in the early twentieth century and in Britain and the rest of Europe in the 1990s as part of the switch from manufacturing to services and from standard commodities to value-added, premium novelties. The consumer boom of the late twentieth century as well as the Internet and digital media were major factors. Everywhere the barriers that had segregated arts and business, imagination and profit were falling. Around the mid-1990s governments realized that the disparate and often fragmented arts, culture, and media sectors provided significantly more jobs and a higher proportion of gross domestic product (GDP) than previously acknowledged. Prompted by Britain’s culture minister Chris Smith in 1998, the creative industries began to be seen as “sunrise” industries just as consumer electronics had been championed by Japan and Taiwan thirty years earlier. In this process people became acutely conscious of the role of creativity as a driver of personal growth and of economic development.

The Chinese government formally endorsed the cultural industries (wenhua chanye) at the Ninth People’s Congress in 2001. Within a few years some thinkers had followed international practice by widening the concept to creative industries (wenhua chuangyi chanye). Shanghai launched its International Cultural and Creative Industries Expo in 2005. Beijing and Shenzhen followed in 2006.

Cultural and Creative Industries Linked

The linking of cultural and creative industries reflects a universal ambivalence about the relative roles of art, culture, creativity, and innovation. No theorist has pinned
down these concepts or shown satisfactorily how they relate to each other, leaving governments to pick and choose according to their own circumstances. China sees culture as something historic, collective, materialist (e.g., artifacts), and more easily controllable. It sees creativity as something novel, disruptive, and more abstract. In Beijing the more conservative thinkers divide activities into a cultural box and an innovation box and leave no room for the kind of individual creativity that might drive art, design, and business with equal vigor. But outside Beijing many provinces and cities seem more relaxed about using the term creative industries.

In this attitude China reflects Asian attitudes to creativity and innovation that are largely based on tradition and collectivism, and are fundamentally different from the West’s. It is true that since the 1950s some Asian countries have been open to U.S. ideas, but China is both more resolutely determined to maintain its own national integrity and more ambitious in its international competitiveness.

As a country China has the oldest continuous culture in the world. At times it has also been the world’s most innovative culture, but its inventiveness in arts and technology declined sharply around the 1700s and did not re-surface until the last few decades. The creative economy that now shapes China’s arts, design, media, and entertainment is profoundly influenced by this history.

China exemplifies the Asian values of authority, hierarchy, and tradition. It tends toward centralized rulers, whether an imperial dynasty or the Communist Party. For centuries rulers permitted independent thought only if it supported their worldview and could be administered by local bureaucracies. This authority accumulated tradition. One result is the love of learning by rote and by copying, and of putting the new copy back into the public domain (some Chinese thinkers therefore disdain an author’s intellectual property rights as being antisocial). Some Western commentators have picked up this Asian trait and decided that Asians are not creative, but this conclusion is too crude.

A new idea must be shown in advance to have beneficial social effects before resources are committed. Harmony is all. A Chinese official wanting to launch a new TV channel will refer glowingly to his city’s ancient history and the need for harmony before discussing the business plan. The Chinese tend not to believe that worthwhile ideas might come from people working on their own, especially someone at the margin who does not subscribe to government thinking. Governments do not want individuals creating their own ideas, symbols, and narratives, making their own meanings, or establishing a community of interest with consumers. To this extent China’s creative process is directly opposed to the Western process in which people choose their own path and ask their own questions. This difference, and its effects on both China and the West, will have profound effects on global cultures and international business in future years. China is the only country capable of challenging U.S. assumptions about how to do business. It is hard to foretell the outcome, which will depend on whether and by how much China and the West modify their practices.

**Political Influence**

The influence of local politicians at provincial, city, and district levels is another important factor. In China a local official’s decision to invest public funds, allocate land, and facilitate contracts has considerable impact on which businesses and individuals thrive. The success of Beijing’s initiatives therefore depends on local politicians, who often have little sympathy with or understanding of creative business. These politicians have much more influence than do Chinese entrepreneurs and managers. In the West, in contrast, many new ideas and companies come about because local businesses have raised their own money and taken action.

Although it is difficult to generalize, these principles usually have their greatest effect on mass markets (TV, radio, publishing, the Internet, video games, advertising, and film) and are less constricting in sectors that affect small groups (art, fashion, and high-end architecture, and interior design).

The history of China’s creative economy emerged out of the reform movements of the 1970s. One source was the obvious need for design and advertising to stimulate modernization. China Central TV (CCTV) and Shanghai TV started showing advertisements in 1979. Another source was the spread of systems thinking and digital technology. Chinese intellectuals and artists, often working with the Chinese Academy of Social Sciences, vigorously explored the new theories of knowledge and network thinking and
their role in economic development, leading to intense debates. The slackening of censorship encouraged semi-independent magazines to publish news, stories, and essays (although fiction remains a minority niche). The statistics bureau started to publish data on arts and culture in 1985.

Key events in national policymaking were the Ministry of Culture conference in Qingdao in 1991 and the ministry’s first reference to “cultural industries” in 1993. The Fifteenth National People’s Congress (2000) permitted small-scale businesses, including design, TV, animation, and publishing companies. The Tenth Five-Year Plan (2001–2005) prioritized knowledge and information and referred to “cultural industries,” by which it envisaged state-led manufacturing innovation rather than independent thinking. In 2002 the Sixteenth National People’s Congress said the Communist Party should enhance the cultural industries’ strength and competitiveness.

The Chinese Academy of Social Sciences began publishing its annual *Blue Book on China’s Cultural Industries* in 2002. The Eleventh Five-Year Plan (2006–2010) gave more attention to arts and culture and began to speak of the creative economy. By 2007 cultural and creative industries were common topics in the national dialogue on the future of China, although considerable confusion existed about how creativity fits within the Chinese model of development.

**Creative Cities**

By 2008 the top four municipalities and most second-level cities had proclaimed themselves to be creative cities, albeit with interpretations different from city to city. Although obviously intrigued by Britain’s promotion of its creative industries in 1998, China, like other countries,

---

has been selective in what it imports. Many cities used the phrases “creative cities” and creative industries” loosely to indicate any activity or urban site that has echoes of Western-style branding, retailing, and the arts. Shanghai is notable for converting about seventy warehouses and factories into creative clusters. Many state-owned enterprises that own buildings that are no longer viable want to turn them into a “creative space,” although their reasons are often to follow Beijing and increase their property’s value rather than to meet demand. A few succeed, such as Beijing’s 798 and Shanghai’s M50 art complexes, but many others are less certain of their markets. Too often such development is driven by property speculation rather than the ideas and needs of potential users. The label creative is often applied indiscriminately to both production (e.g., animation production companies) and to retailing (e.g., a shopping mall).

No national census of China’s creative sectors exists. Many cities have published their own research, although unfortunately each city uses a different definition, often driven by its desire to optimize the importance of its own sector relative to that of other cities. Some cities include exhibitions, tourism, and food and beverage. Shanghai uses five categories: (1) culture and media, including art, performance, film, TV, and radio; (2) architectural design, including architecture and related skills such as structural engineering and interior design; (3) research and development design, including industrial design, software design, fashion, and advertising; (4) planning, including market research, some financial services, and conferences and exhibitions; and (5) leisure, including photography, sport, and tourism.

Beijing, Shanghai, Shenzhen, Chongqing, and Guangzhou (Canton) claim that 7 to 10 percent of their GDP is attributable to the creative economy, which means they are on a level with major Western cities. Elsewhere the figures are smaller.

In terms of markets the creative sectors may be split into four groups: sectors that most visibly express China’s history and culture (traditional art, museums, crafts, poetry, calligraphy, and traditional performance); sectors that reach the mass market (radio, TV, newspapers, and books); sectors that appeal to sophisticated urban populations (design, fashion, and magazines); and the infrastructure industries (architecture, interior design, furnishings, electronic communications, and online services).

The Internet plays a vital role, especially among young people who access it through mobile devices and computers. Chinese youth are as keen as their Western contemporaries to talk, share, blog, and post. Content-creating software is widely available, usually pirated, and numerous websites support online communities such as Neocha 新茶 and Douban 豆瓣. Although the government monitors these sites, it seems generally relaxed so long as users do not challenge Beijing’s politics. The main themes are art, design, music, and fashion, and although the focus is China, the references also cover Europe and the United States.

This analysis of China’s creative economy has to reconcile the country’s enthusiasm for creativity as a magic potion for economic growth and its uncertainty about what creativity is and how to manage it. Some conservative thinkers take refuge in creativity as historic culture, but this usage, however impressive, will never be sufficient to transform a whole economic system, as is China’s ambition. Given China’s social and economic strengths and its vast population, it is likely that domestically its creative economy will grow rapidly and substantially. The more interesting question is this: What will be China’s effect on the West’s understanding of what creativity means and how to use it? The West assumes that its approach is the best one and shows little inclination to change, but the competition between the two models will be fierce.

Further Reading

China’s first comprehensive legal code was set forth during the Tang dynasty (618–907 CE) and served as the model for many years of imperial rule. Traditionally, Confucianism played a huge role in ensuring a relatively crime-free society. Since the reforms of 1978–79, and the subsequent imbalance between rich and poor, crime has been on the rise.

The Chinese way of life dates back more than five thousand years, and traditions from the past continue to influence life in the twenty-first century. In 1949 China became a Communist nation with the establishment of the People’s Republic of China (PRC), and the current political and economic structures and processes are, to a significant degree, the product of dramatic social changes since then. Most important, since 1978 China has undergone economic reforms that started to transform the national economy from one based on state control to one based on market capitalism. These transformations have increased personal freedom and wealth for many Chinese. They have resulted in the concentration of wealth and increases in economic equality—and in crime.

Confucianism and Social Order

Confucianism has been the longest lasting influence and among the most important influences on Chinese values and social order. In Confucius’s view society is hierarchical, with the concept of li being the behavioral norm for people of superior status and inferior status. According to li it is virtuous for the inferior to respect and obey the superior. In an extreme interpretation of li by some later Confucians, “A minister will oblige should the emperor order him to die; a son will oblige should his father ask him to die” (Xia 1995, 16). Confucius (551–479 BCE) maintained that if all individuals acted according to li, order would prevail without conflict. Confucianism fostered an orderly society based on suppression of self-interest and acceptance of authority. Lawsuits, for example, were deemed confrontational and disruptive, and the Chinese continue to prefer to avoid resolving disputes in courts.

Traditional law in ancient China was largely set forth in the criminal code and targeted behaviors that were seen as threatening to the status quo. During the Tang dynasty (618–907 CE) the first comprehensive legal code was set forth, and subsequent dynasties adopted the code without changing its fundamental elements. The use of informal methods of social control was emphasized and remains important today.

After China was politically unified in 221 BCE, centralized government control became the dominant political structure, and all aspects of the judicial system were under government control. The criminal justice system was managed by government officials, and judicial authority was one of the powers delegated to local officials by the central government. The inseparable relation between judicial function and other authority made it impossible for courts to appreciate equity in justice.
The Legal System of the PRC

China’s modern history began with the fall of the Qing dynasty in the revolution of December 1911 and the abdication of the emperor in February 1912. Civil war and foreign aggression fragmented the new Chinese Republic until 1949, when the country was unified under the Communist government of the PRC. The new regime modeled the country’s judicial system after that of the Soviet Union’s. The system consisted of four components; each was under a centralized administration in Beijing:

- The police were responsible for investigation, detention, and preparatory examination of criminal cases. Police are under the command of the Ministry of Public Security (MPS).
- Procurates were responsible for approving arrests and initiating public prosecution. Procurates are under the Ministry of the Supreme People’s Procurate.
- Courts were responsible for adjudication. Courts are subject to the administration of the Supreme People’s Court.
- Corrections were under the Ministry of Justice.

Because the Communist Party Central Committee is the true locus of power in China, party ideology and politics determine the nature of the criminal justice and judicial systems.

Lawlessness During the First Three Decades

From 1949 to 1979, the PRC operated a legal system with neither a criminal code nor a criminal procedure code. The major criminal legislation during this time was the Act for the Punishment of Counterrevolutionaries, promulgated in 1951. The act defined many deeds as counterrevolutionary or subversive. Article 16 established the principle of crime by analogy; behavior unspecified in the act could be punished according to analogous specified crimes in the act. Article 18 enabled a retroactive application of the act to crimes committed before the PRC was established. Conventional crimes, such as murder and rape, and their penalties were allegedly defined in unpublished regulations. Without legal guidelines to follow, the people’s courts often made no reference to the law and specific provisions as the basis of a given judgment. The Arrest and Detention Act of 1954 is the only known document from this time detailing some safeguards against arbitrary arrests or detention. In practice they were frequently ignored.

With political control as the rationale and the absence of criminal law and legal procedure, the government had thousands of individuals arrested and punished for ideological reasons. Many were convicted as Rightists or black (hei, meaning corrupt or illicit) elements, such as former landlords and rich peasants. In 1966 Mao Zedong instigated the Cultural Revolution, encouraging revolutionaries to destroy all establishments in defense of true Marxist socialism. As a result mobs and thugs acted as free agents of justice from 1966 to 1976. They purged, abused, convicted, and executed thousands of innocent people and destroyed numerous homes and personal possessions without having to employ judicial process. During the revolution many senior party leaders were accused of being capitalist followers, reactionary authorities, counterrevolutionaries, and revisionists. Their own victimization and humiliation motivated them to steer the party away from Mao’s obsession with ideological wars after Mao’s death in 1976.

The New Order Since 1979

After thirty years of lawlessness, the PRC initiated efforts to develop a rational system of criminal justice. In 1979 the National People’s Congress (NPC) enacted China’s first criminal code and criminal procedure code. The criminal code had 192 articles and classified crime into eight categories, including crimes of counterrevolution. Most of the laws and decrees promulgated since 1949 remained in force. In 1990 the Standing Committee of the Congress established the prohibition of drugs. In 1997 the NPC amended the first criminal code by abolishing the use of analogy as a general principle—stipulating that a crime must be legally defined before a conviction can be imposed, and abolishing the crime of counterrevolution and replacing it with the crime of harming state security. Although this might seem to be a mere name change, it does provide real progress. For example, superstitious practices are no longer listed as a type of crime. The
criminal code provides five principal penalties, including the death penalty, and three accessory penalties. Article 5 stipulates that all death sentences are to be reviewed by the Supreme People’s Court for approval. The death penalty does not apply to offenders under eighteen and females pregnant at the time of trial or sentence.

Criminal trials in the PRC resemble those based on the civil law legal tradition. Instead of a trial jury, a panel of judges and people’s representatives decides the guilt of the defendant and the sentence if the defendant is found guilty. The number of judges and people’s representatives increases as the administrative level of the court increases. In these people’s courts, people’s representatives have equal rights with judges. If opinions of panel members diverge, the minority defers to the majority. The minority opinion is entered into the court transcript. Law is more than a legal vehicle in the PRC. Criminal trials sometimes are held in public areas to draw large crowds for educational purposes.

**Crimes**

In the PRC police are the only regular source of national crime information. Crime statistics were not available to the public before 1986. Since then, the Ministry of Public Security has provided such information to the annual publications *Social Statistics of China* and the *China Yearbook of Law*. Before 1991, the official statistics covered murder, injury, robbery, rape, larceny, fraud, and counterfeiting. After 1991, statistics are also provided for the three emerging crimes of kidnapping, smuggling, and drug offenses.

China has experienced dramatic increases in crime rates since 1979 when economic reforms were initiated. But changes were distinct before, during, and after the Cultural Revolution, as indicated by the following statistics: Between 1951 and 1965, China’s annual crime rates per 100,000 population varied between 30 and 60. Rates then rose from 56 in 1978 to 89.9 in 1981 and to 200 in 1990. The average annual crime rate increase was 2.2 percent before the Cultural Revolution (1966–1976), 10 percent during the revolution, and 12 percent in the reform period between 1979 and 1991. During the more aggressive reform period of 1985 to 1991, the average annual increase was 32 percent. The Cultural Revolution, however, was an unusual time. Because of mob justice, crime statistics for this time may not be comparable to crime statistics for other times. Although there have been increases in traditional crimes, new crimes, and especially drug offenses, account for much of the increase. Court records indicate an average of 21 percent annual increase in drug crimes from 1991 to 1994 nationwide. Regardless of the...
upward trends, China’s crime level is low by international comparison. In the 1994 International Crime Victimization Survey, China’s one-year overall victimization rate was 12.6 percent, which was the lowest in the developing countries surveyed and was lower than the lowest rate in the developed countries surveyed.

The emphasis on economic development has transformed not only the economic lives of the Chinese people but also the country’s cultural ethos as well. Being wealthy, no longer chastised as bourgeois decadence, is now glamorous and desirable. Under the initial reform policy of “let some people get rich first,” many public officials and their family members are certainly among the first to make a fortune. This is often achieved by exchange of power for bribes and personal benefit in various forms. Temptations are particularly irresistible in the public sector where officials have discretion to allocate government-monopolized resources or information, such as goods at undermarket price, loans, and market-entry opportunities. Corruption, as an uninvited guest of the economic reforms, has plagued the reform era. In 1997 150,000 corruption cases were reported to authorities, triple the number of reports in 1993. Studies have shown that while reported corruption cases have been leveling off, more cases after 1993 involved senior party officials and much higher financial values. The rampant corruption problem is a major source of growing domestic discontent and social unrest amidst China’s impressive economic growth.

Punishments

Thought-and-labor reform has been the guiding ethos of the Chinese penal system. China boasted of a 2 percent recidivist rate before economic reforms. The penal system alone, however, could not achieve such success without societal supports. The Chinese population was rather immobile due to the difficulty in changing jobs and residence. After serving time in the penal system, most ex-offenders had to return to their previous workplace, demoted, a requirement that ensured employment. On the other hand, the workplace, where everyone knew the ex-convict, became a powerful force for shaming, rehabilitating, and controlling behavior. The effect of thought-and-labor reform has been weakened since 1978. Economic liberalization has produced a dramatically different world than the one that supported reform-through-labor programs. Employment is no longer guaranteed, even for law-abiding citizens.

Five types of correctional institutions are used in the PRC: prisons; labor reformatories; juvenile reform houses; detention houses for those who have been sentenced in a television show, 1979. Juvenile reform houses are one of five types of correctional institutions in use in the People’s Republic of China. Photo by Joan Lebold Cohen.
sentenced (*juyi*); and detention houses for those awaiting trial (*kanshou*).

In Chinese law, detention is divided into two types. One is administrative detention, in which the detainee goes through labor education in a reformatory institution. The other is criminal, with prisoners undergoing labor reform within the prison sector. The first type is not criminal punishment, and its education is a form of penalty for public disorder offenses, such as prostitution and drug addition. These detention centers are under the direct control of police. They are mostly in no condition to provide real education because of financial strains. As a result police have discretionary power and flexibility over their operation.

The prison system operates through two administrative divisions: the Labor Reformatory Administration, under the Ministry of Justice, and the local labor reformatory bureaus, under the Justice Bureau in the provinces, autonomous regions, and municipalities. The bureaus oversee labor reformatory work. They also oversee prisons in their own jurisdictions.

Prison inmates are offenders given death sentences with a two-year suspension; offenders sentenced to life imprisonment; offenders who must serve at least ten years in prison before release; foreign offenders; and female offenders. Offenders given other sentences are held in reform-through-labor teams. Juvenile reformatories provide special correction services to juvenile offenders.

In 1991 there were 684 prisons, including labor reformatory teams and juvenile reformatories. The daily average population in correctional institutions was more than 1.2 million, 2.15 percent females and 8.4 percent minorities. The estimated annual admission was 250 per 100,000 population. Violent offenses accounted for 34.4 percent, property crimes for 60.6 percent, and drug crimes for 0.8 percent. The remaining 4.2 percent were other crimes. By 1993 those who committed other crimes had increased to 18.7 percent, with 33.6 percent convicted of violent crimes and 48 percent of property crimes.

Chinese correctional policy holds that all offenders can be reformed. Work is believed to be the most effective reform method. By law, all inmates capable of working must work. Those who are not capable of working because of age or illness or unfitness are spared from work. In 1990 about 10 percent of the prison population did not engage in work activities.

Education is one of the most emphasized prison programs. In 1981 the government included prison education in its national education program. By 1991, 72.8 percent of prisons and labor reformatory branches had established special education programs with a dean, a faculty office, and a curriculum. (The branches are operating units that house and supervise individuals going through labor reform.) Some teachers are chosen from those prisoners with a higher education level. The curriculum includes cultural, moral, legal, and technical education. Inmate students study two hours a day. After passing locally administered exams, students receive an educational certificate equivalent to those issued by educational institutions outside the prison. Some prisoners enroll in distance-learning programs and take higher-education exams for self-study.

An important part of prison education is vocational programs. In 1991 more than 561,000 participated in vocational courses, representing 83 percent of the total number of eligible prisoners. Labor departments issued 546,000 proficiency certificates for various technical skills.

A 1992 national study of 159,177 adult offenders released from prison from 1982 to 1986 indicated the success of China’s correctional policies. It showed an overall recidivism rate of 8.28 percent in a three-year follow-up period. Offenders holding temporary jobs had a 5.13 percent recidivism rate, whereas those unemployed had a 15.9 percent rate. Offenders returning to their original workplace or being employed in private enterprises had the lowest recidivism, with 1.9 percent and 2.3 percent, respectively. Compared to the rates in industrialized countries, including Japan, these are much lower rates.

**A Continuing Problem**

The Chinese government acknowledges alarm at the increase in crime. It attributes such increases to the capitalist influence of the Western world and to changing values in the Chinese people in a new economy. The growing privatization and social mobility have stimulated individualism and increased the emphasis on profits. Also, an increase in social inequality and the loss of a guarantee of lifetime employment have become major causes of social instability.
China has made efforts to strengthen informal social control at the grassroots level. Neighborhood committees are an example. Private citizens in these committees watch for problems, mediate disputes in and between families, and work with neighborhood police. But there is a steady weakening of other informal mechanisms, such as control through job stability and immobile residency. Reducing informal social control will inevitably lead to an increased use of police and punishment, as has occurred in many developed societies. The Chinese government periodically launches campaign-style crackdowns on both street crime and official corruption. A major campaign measure is increasing the use of police and capital punishment. While the public approves of this get-tough policy, the effectiveness of such a strategy is questionable because it does not tackle the social conditions that breed crime and recidivism.

**Further Reading**

Although China is one of the world’s oldest civilizations, its criminal justice system has fallen behind that of other nations. The complicated system is plagued by lack of education, serious corruption, and new and more serious crimes than in the past. Often, criminal suspects are denied basic rights taken for granted in the West. Reformation of the Chinese criminal justice system remains on the horizon.

Viewing China’s criminal justice system through a Western lens, it is easy to see only its deficiencies. The system is marked by long periods of confinement before trial and a high rate of confessions. Criminal suspects have no right to refuse interrogation, enjoy no presumption of innocence, and have no right to confront their accusers or force witnesses to testify in their defense. The right to counsel is extremely limited in the investigation phase of a case, and although there is a right to counsel at trial, that right is restricted by limited opportunity of the defense to conduct its own investigation.

While these are major deficiencies in the system, it should be noted that China’s current criminal justice system is still developing. Since the 1980s, as it has moved toward a socialist free market economy, China has experienced new types of crimes as well as crimes of a magnitude that did not exist under the more totalitarian communist rule. Public corruption, economic crime, computer crime, narcotics trafficking, robbery, and murder are all more prevalent than they once were. China’s criminal justice system is burdened with the dual challenges of increased crime and the need for modernization.

A New System

China’s Criminal Procedure Law (CPL) went into effect in 1980, during the early days of the reform era led by Deng Xiaoping. Further amendments went into effect in 1997. Since 1980, legal and judicial institutions have been reestablished and law schools have reopened. The CPL forms the basic framework of criminal law in China, yet, in many ways, the criminal justice system remains a work in progress.

Prosecuting Authority

The Chinese agency responsible for prosecuting criminal cases is the People’s Procuratorate (Renmin Jiancha Yuan). The procuratorate’s historical roots go back 2,000 years to imperial China. Chinese emperors employed an official with the title of imperial censor or imperial secretary (yu shi), who acted as the eyes and ears of the emperor and reported any misconduct or corruption by government officials. Gradually, this position evolved to the role of public prosecutor in cases involving crimes committed by government officials. The yu shi also exercised a supervisory role over the judiciary, ensuring that judges acted according to the law.

Today, the procuratorate is one of five branches of
government. In theory, the procuratorate is charged with ensuring that the other civil branches of government act according to the law. Procurators are responsible for deciding whether someone should be formally arrested (daibu) and formally charged (qi song).

Like most Chinese government bodies, the procuratorate consists of a hierarchy, with the Supreme People’s Procuratorate (SPP) at the top. The SPP handles matters in the Supreme People’s Court and reports directly to the National People’s Congress. Beneath the SPP are lower procuratorates that correspond to the lower levels of local government.

These procuratorate offices interact according to hierarchy. The CPL permits two trials and an appeal by either side from the verdict of the second trial. Generally, each successive proceeding must be brought at the next highest level. For example, a case initiated at the county level will be handled by the county procurator’s office in the basic people’s court of that county. If there is a second trial, it will be heard by an intermediate people’s court, where the case will be handled by the city procuratorate. An appeal would be handled by the provincial procuratorate. Any further proceeding would be in the Supreme People’s Court, with the prosecution handled by the Supreme People’s Procuratorate. There are also special procuratorates for the military and for railway transportation.

CRIMINAL INVESTIGATION

Most criminal offenses in China are investigated by the Public Security Bureau, which is part of the executive branch of government. Criminal offenses committed by government officials, employees, and agencies, however, are investigated directly by the procuratorate. The procuratorate’s anticorruption unit conducts investigations of bribery, embezzlement, and other public corruption. The procuratorate also has a government employees’ misconduct unit, which investigates other criminal conduct committed by government workers in their official capacity. Cases of abuse of power, dereliction of duty, and police brutality are investigated directly by this unit of the procuratorate. In addition to these two units, each procurator’s office also has units that handle arrest approval (usually reviewing daibu requests made by the police), criminal prosecution, citizen complaints, appeals and petitions, research, internal discipline, and administration.

A private citizen also has the right to bring a criminal case directly to the people’s court.

The first stage in any criminal case is the preliminary investigation, which begins after a criminal activity is reported. The police and the procuratorate receive these reports. Citizens have the right and the duty to make such reports.

A criminal case begins when the police or the procurator files a case. The standard for filing a case is somewhat vague. The CPL provides that a case should be filed for investigation when the responsible official discovers facts of a crime or criminal suspects or, after examining a citizen report or complaint, the official believes that there are “the facts of a crime and criminal responsibility.” The CPL proceeds on the assumption that it is possible, even at this early stage, to learn whether there are the facts of a crime. The CPL does not even entertain the possibility that there may be some evidence of a crime and some evidence to the contrary and thus a need to investigate further.

Filing a case is both a symbolic and practical step. The act of filing provides some official acknowledgement that a crime has been committed. The practical significance is that only after a case is filed are investigators permitted to use the investigative techniques set out in the criminal procedure code, which include detention of the suspect.

Once a case is filed, the investigating authority may use the full range of investigative techniques available, including compulsory measures, which restrict the liberty of the suspect. Chinese law seems to favor confining anyone suspected of a crime, even before criminal charges are filed. The investigating authority has the right to determine whether a suspect should be incarcerated or released. (This is in contrast to the American system, which requires probable cause before the issuance of search and arrest warrants.)

These compulsory measures can take several forms. The first is a compelled appearance (ju chuan). Once a case file is opened, the police may order the suspect to the police station for up to twelve hours of questioning. During this period the suspect has no right to consult with anyone.

After the initial police interrogation, the suspect is notified of his or her right to contact a legal representative or family member. If the suspect has a legal representative, the police have a duty to notify that representative. During this stage the representative, who can be either an
attorney or a lay representative, has a right to be present but may only advise the suspect generally about the case and suspects’ rights.

Before the 1997 reforms, the time limit for holding a suspect for interrogation was twenty-four hours. However, the police routinely initiated a new twenty-four-hour period as soon as the previous one expired, rendering the time limit meaningless and permitting unlimited interrogation. Under the current law, if the police choose to hold a suspect beyond the initial twelve-hour period, they must use another compulsory measure, detention (juliu).

Juliу provides that the police may detain a suspect from three to thirty-seven days if the suspect is

1 preparing to, in the process of, or discovered immediately after committing a crime;
2 is identified as having committed a crime by a victim or an eyewitness;
3 is found with criminal evidence on his or her person or residence;
4 attempts suicide or escape after committing a crime;
5 is likely to destroy or falsify evidence or tally confessions;
6 does not provide a true name and address, and identity is unknown; or
7 is strongly suspected of committing crimes from one place to another, repeatedly, or in a gang.

An estimated 90 percent of suspects are detained during investigation.

After the initial period of detention expires, the only way investigators can lawfully continue detaining a suspect is by obtaining permission to formally arrest the suspect. Technically, only the chief procurator can approve a formal arrest. In practice, however, each procurator’s office has a special section designated to handle daibu requests from investigators.

**Formal Arrest**

Daibu has a different meaning in Chinese than it has in English. Daibu refers not to placing a suspect in custody but rather to lodging a formal charge against him or her. And unlike in the United States, in China criminal suspects or defendants have no substantive rights.

To approve a formal arrest, the procuratorate must find that there is evidence to support the facts of a crime; that the suspect could be sentenced to imprisonment; and that being free the suspect poses a danger to society. Exceptions are made for suspects who are seriously ill, pregnant, or nursing.

Once the case is transferred from the police to the procuratorate for prosecution, the procuratorate has one month to decide whether to prosecute, a period that can be extended two weeks in a complex or major case. But if the procuratorate cannot decide within this time, or if it decides that further investigation is warranted, it can send the case back to the police for further investigation. In that case the police have up to an additional month to complete their investigation. If the procuratorate decides to bring the case after the second presentation by the police, it is conceivable that four months will have passed by the time that decision has been made.

Even after the second presentation, the procuratorate may decide that further investigation is warranted, but it may not send the case back more than twice. Thus a total of up to seven and a half months may pass before a decision to prosecute is made.

The 1997 amendments to the CPL allow for two other measures short of detention: release on bail and residential surveillance. Within twenty-four hours of detention, the police must notify the suspect’s family, lawyer, or representative. These representatives may then apply for bail (qu bao hou shen) or house arrest (jian shi ju zhu) on the suspect’s behalf. The decision to allow a suspect out on bail or house arrest is made by the investigating agency, typically either the police or the procuratorate. The Chinese system of bail places a great deal of risk on the guarantor. If the suspect does not appear as required, the guarantor not only forfeits whatever property has been posted as security but also may be subject to arrest. A suspect may be on bail awaiting trial for up to twelve months or under house arrest for up to six months.

The basic method of investigation after arrest in China is for the police to interrogate a suspect and then investigate whether the suspect’s information is true or false. After the investigation, the police may resume interrogation of the suspect and, if necessary, investigate further. All suspects must be interrogated within twenty-four hours.
of detention or arrest. Interrogation conducted following a forced appearance is limited to twelve hours.

Two investigators must be present during interrogations, and a written statement must be prepared and signed by the suspect. When interrogating a suspect, the investigators must first ask whether the suspect has committed any crime. Then they may ask other questions. The suspect must answer truthfully. No right to remain silent exists, and confession is an important component of a criminal investigation. The CPL forbids extorting confessions by torture and prohibits collecting evidence by threat, enticement, deceit, or other unlawful means, but there is no procedure for the suppression of unlawfully obtained evidence.

A suspect may hire a lawyer only after the initial interrogation. At this stage the lawyer’s role is limited to providing the suspect with legal advice and filing petitions and complaints on his or her behalf. The lawyer may not yet assist the suspect in preparing a defense. If the case involves state secrets, a vague and adaptable concept under Chinese law, the suspect may need the approval of the investigating authority before hiring a lawyer.

Investigators are authorized to conduct searches without judicial approval or the approval of any outside agency and without reference to any standard of proof indicating the presence of evidence of a crime. Other investigative techniques expressly sanctioned by the CPL include the questioning of witnesses, inquests and examinations, seizure of evidence, and expert evaluation. Chinese law prohibits the use of torture, threats, enticement, or deceit to obtain evidence.

Although procurators have the authority to conduct wiretaps and mail searches, such methods are used infrequently and require high-level approval within the agency conducting the investigation. Judicial approval is not needed. They also rarely used the testimony of one

criminal to convict another, in part, because they do not like to provide leniency in exchange for cooperation. Police might use undercover techniques if illegal products such as drugs or pirated compact discs are offered for sale to the public. In those circumstances a police officer posing as a member of the public might make an undercover purchase.

After gathering evidence, the investigators submit the evidence to the procuratorate section in charge of approving prosecutions. At this stage, the suspect is entitled to consult with his or her attorney fully and confidentially.

After determining the facts of a crime, the procurator must interrogate the suspect and his or her representative, and consult with the victim and his or her representative. If during this review the procurator discovers that any illegal method was used during the investigation, the procurator may refer the conduct of the investigator to the appropriate disciplinary authority. If the misconduct rises to the level of a criminal offense, it is referred to the appropriate section of the procuratorate for criminal investigation. The procurator is also charged with ensuring that all crimes and all criminals have been charged, ensuring that the investigation was lawfully conducted, and deciding whether the case has incidental civil actions.

Once the procurator decides to initiate prosecution, the case comes under the jurisdiction of the appropriate level of the people’s court.

**Trial Procedures**

*Shenpan,* commonly translated as “trial” should more accurately be translated as “adjudication,” as Chinese trials generally do not have live witnesses subject to cross-examination and defendants do not enjoy a right to remain silent. The word trial sometimes leads to misunderstandings and disappointed expectations.

Trials are generally conducted before a panel of three decision makers, made up of at least one professional judge, who may or may not have received legal training, and two citizen assessors, or, in some cases, three professional judges. Cases are decided by majority vote.

Trials begin with the court questioning the defendant about his or her identity, status, and the basic progress of the case to that point. The defendant is also given an opportunity to request the removal of a judge or prosecutor because of a conflict of interest or prejudice. The prosecutor then reads the charges, and the court asks the defendant for a response. The prosecutor then reads off each piece of evidence, and the court asks the defendant and the defense lawyer if they have any opinions concerning the evidence. If the prosecutor calls a witness, or if the victim is a party to the case, the defendant and the defense attorney may each question the witness and the victim, and the victim may question the defendant.

After the prosecution has presented its evidence, the defense presents its evidence. Then the prosecution, the defendant, the victim (if any), and the defense attorney all have an opportunity to argue the case. The defendant is given the last opportunity to speak. Finally, the judicial panel retires briefly and returns to announce a verdict and sentence.

**Sentencing**

The court generally reaches a verdict and announces a sentence as part of the same trial proceeding. This makes for a difficult defense argument. On the one hand, the defense may want to contest the facts. On the other hand, the defense does not want to appear to have anything but a remorseful attitude to receive more lenient treatment in the likely event of a conviction. The standard of proof at trial is that the facts are clear and the evidence is sufficient and reliable. The defendant may be found innocent outright or because of insufficient evidence. If a defendant is acquitted, Chinese law provides for compensation to be paid to the defendant for any period of incarceration found to have been unlawful.

Procurators have the authority to request an adjournment midtrial to obtain additional evidence. Judges may also, on their own, adjourn the trial and conduct their own investigation outside the courtroom. In difficult cases the court may consult with the chief judge, who may turn the case over to a judicial committee for a decision.

The Chinese Criminal Procedure Law has no concept of a trial as a proceeding to assess credibility and determine the truth based upon an open court evaluation of all the evidence. Witnesses are not required to appear in person. The ultimate decision makers may be authorities who did not personally preside at the trial to hear the evidence. The standard of proof, the lack of a requirement for live testimony, and the lack of a right to silence, coupled with long
periods of precharge incarceration and the opportunity for those who did not hear the evidence to make a decision, all make trials into less a search for the truth than an opportunity to eliminate all conflict before the trial. There is no notion that the procedures are designed to allow a fair determination of the truth by allowing each side to attack the other’s evidence. Instead, the truth is considered knowable, and it is the responsibility of the police and prosecutors to determine the truth and present it in court.

Chinese sentences can be extremely harsh by Western standards. For example, Chinese law authorizes the death penalty as a punishment for a host of crimes in addition to murder, including rape, narcotics trafficking, embezzlement, bribery, and financial fraud.

Reforms in Store

Although outright challenges to the Communist Party are not tolerated, many people are working within the existing political structure in China to accelerate the speed and broaden the scope of legal reform. In fact, official policy encourages reform. However, the road to reform is a difficult one.

Although the number of qualified legal experts in China is growing, there is still a shortage of trained legal talent throughout the system. Most procurators are not even college graduates, let alone law-school graduates. The same is true of judges and lawyers. Moreover, trained legal specialists face strong economic incentives to apply their talents in more lucrative fields, such as international trade and finance. Any significant legal reform is bound to make the job of prosecuting, defending, and judging cases more difficult, complicated, and challenging. Without sufficient numbers of trained legal experts, any legislative reform would be futile.

Corruption represents perhaps the biggest obstacle to reform. Corruption is also the number one political issue on the minds of the Chinese people. All the reforms in the world will be of no effect if the system is corrupt and lacks the confidence of the people.

Despite uncertainty surrounding the speed and shape of reform, one fact remains clear: there will be reform. The reforms may be deemed insufficient when measured against American standards of due process, but when compared to the arbitrariness and anarchy of earlier times, they are quite significant. China now has a tradition of legal reform, with many new reforms on the drawing table. The criminal justice system is very much a work in progress.

CUI Jian

Cūn Jiàn 崔健

b. 1961  Singer and musician

Cui Jian is China’s first rock and roll star. His song “Nothing to My Name” has become an anthem of loss for the Tiananmen generation who witnessed the crackdown on student dissidents in 1989.

Cui Jian, China’s first rock and roll star, was born to musician parents of Korean descent and raised in Beijing during the Cultural Revolution (1966–1976). He began learning trumpet at age fourteen and in 1981 joined the Beijing Philharmonic Orchestra. In his spare time he explored popular music.

Although Cui’s first album was a largely unnoticed collection of pop music covers (Lanzigui, 1984), he soon began writing his own music and lyrics and developing his trademark gravel-voiced style, drawing inspiration from Western rock bands such as the Beatles, the Rolling Stones, and the Police. In Beijing in May 1985 Cui performed one of his first rock songs, “Nothing to My Name,” a disconsolate ballad melding Western rock with traditional Chinese melodies and instrumentation. The performance rocketed him to stardom, and the song remains his signature hit and an anthem of loss for the Tiananmen generation, the youth who witnessed the bloody crackdown on student democracy activists on 4 June 1989.

Cuisines

Pêngrèn 烹饪

Chinese cuisines were developed partly as ways of maximizing security in a world of scarcity and frequent famine, but also responded to the desires of the well-to-do to show off wealth and sophistication. Grain staples are basic, but the distinctive elements are flavorings, including soy sauces, Chinese “wine,” ginger, onion relatives, and peppers. Regional variation is enormous, with four to five major culinary areas and many minority cuisines.

To one-fifth of the people in the world, Chinese food is not something they order from a menu in a restaurant or have delivered to their front door in little white cartons—it’s home cooking.

Chinese cooking is of notably high quality and diversity. However, China was also the “land of famine,” as Walter Mallory called it in 1926, and the cooking has been shaped by scarcity. For thousands of years the vast population of Chinese people lived on grain, with small amounts of vegetables and soybean products. People ate small amounts of meat; many tasted it only on major festival days such as Chinese New Year. Tea and “wine” (in China it is made from grain rather than grapes) were equally rare luxuries. Famine was frequent, and malnutrition widespread, with endemic deficiencies of iron, calcium, and vitamins B and C. As early as 1406 the government issued a manual on how to use roadside weeds and the like during famines. Even now hundreds of millions of people in the rural interior of China live on little more than boiled grain with a few vegetables and little meat.

Foods are cooked quickly at high heat because fuel was always scarce and expensive; stove design and cooking techniques combine to allow a family to cook a full three-course meal on a handful of dry grass. Cooking techniques also spared oil.

However, in much of the Chinese world a spectacular rise to affluence has profoundly changed the cooking, and people often go to opposite extremes, especially those who remember the old days.

China’s population is 93 percent Han Chinese, speaking one or another language of the Chinese language family. Fifty-five officially recognized minority groups also exist, each with its own language (or languages) and culinary traditions. A few generalizations apply throughout. The overwhelming majority of Chinese depend largely on grain, usually wheat and rice. Other foods usually serve as toppings or accompaniments for the grain staple. In the vast majority of meals the grain is either simply boiled (fan) or made into noodles (mian). Bread is common in the north and dominates in the west but is not a major food for most Chinese. Until recently vegetables were the most common accompaniment; cai means both “vegetables” and “dishes in general” in Mandarin (Putonghua), the majority language of China. Chinese cabbages (Brassica spp., in countless varieties) are the most commonly used and widespread; other vegetables include cucumbers, giant radishes, spinach, tomatoes, and many kinds of beans. The meat of choice is usually pork in most of China, but lamb replaces it in the west and northwest, and
fish dominates along the coasts. Fruit was the only common sweet until recently; China has an enormous range of fruits. Today sugar is common and cheap, leading to more diverse but less-healthy desserts.

Native to China, and characteristic of its cooking, is the soybean. Soybeans became important largely within the last 2,000 to 2,200 years because of the invention of bean curd (doufu, tofu) and of fermented bean products such as soy sauce. Bean curd production and soybean fermentation both release more protein, vitamin, and mineral value in the beans. The yeast used in fermentation adds vitamin B-12, an essential nutrient that is otherwise often lacking in Chinese diets.

Throughout China by far the most common cooking method is boiling. Grain and noodles are usually boiled. Soup is the most common dish to eat with grain staples. Drinks, such as tea, are normally boiled. Boiling is usually quick—soups are not simmered long—but complex stews often require hours of cooking. One major boiling type, most common in central China, is red-cooking: cooking meat slowly in a rich stock with much soy sauce, ginger, star anise, and other flavorings so the meat becomes dark red and tender. Second comes steaming: cooking in a closed pot or bamboo steamer above boiling water. Third is stir-frying (chao), the characteristically “Chinese” cooking method in which thinly sliced food is stirred for a short time in a small amount of extremely hot oil. This saves fuel and oil. More fuel-intensive methods like deep-fat frying, baking, and roasting were rare until recently.

The food of the Han Chinese—and minority groups influenced by them—is sharply distinguished by a specific spicing pattern: garlic, green onions, fermented soybean products, ginger, and, often, Chinese “wine.” (Chinese “wine” is made from grain, thus technically a beer or ale, but it is strong and noncarbonated and thus resembles wine, hence the usual translation.) To these are often added chili peppers (especially in the south and west), white pepper (black is rare), and sometimes other spices. Until recently unrefined vegetable oils—rapeseed (similar to canola), maize, peanut, sesame—provided distinctive flavors, completing a flavor mix that was uniquely and distinctively Chinese. These oils are now replaced by refined oil, frequently from soybeans.
Regional Cuisines

Cuisines in China vary by regions. The country’s most important culinary divide is between north and south.

The North

North of the Yangzi (Chang) River valley, wheat generally dominates, but other grains have been important. In early historic times foxtail millet (*Setaria italica*), domesticated almost as early as rice, was the staple. Other millets and sorghums were grown. Wheat reached north China from the Near East by 2000 BCE and began to displace millet some two thousand years later with the coming of good flour-milling technology. After New World food crops reached China in the sixteenth and seventeenth centuries, maize also gained at millet’s expense. Maize is now used largely for animal feed; millet has almost vanished. Rice has been bred to grow in shorter, cooler summers and has spread far north of its historic range. Thus today north China depends largely on wheat, with rice a strong second. Vegetables are less diverse and often were almost limited to Chinese cabbages and radishes among the poor until diversification campaigns began around 1980. The favored fruit was melons, especially watermelons and melons of the Persian (Iranian) type. Jujubes, apples, and pears were locally common. Lamb was as common as, or more common than, pork in the drier areas.

Grain in the north is much less apt to be simply boiled. Rice and millet are treated that way, but wheat is ground into flour and then made into noodles, bread, or dumplings. Baked loaves of the sort known in Europe did not exist in traditional times. Baked bread was of the Persian form: flat, often layered sheets, often sprinkled with sesame seeds, and baked in a large jar or much larger underground oven. Today bakers burn firewood, clear out the ash, and bake the bread (usually stuck to the walls) in the residual heat. Large breads baked on racks are typical in the northwest, but elsewhere the breads are small—miniaturized Persian flatbreads known as *shaobing* (roasted cakes). More common in most of the north are large unfilled dumplings, steamed instead of baked. These are the staple foods in some areas. They are known as *mantou*, a word formerly used for smaller filled dumplings and cognate (of the same or similar nature) with words for these latter items in neighboring languages (e.g.,

Dumplings, a favorite Chinese food and a specialty of southern China, are being steamed in a stack of bamboo containers over a fire in a metal brazier. Dumplings are made of wheat or rice flour skins stuffed with meat, vegetables, and sweets. Photo by Joan Lebold Cohen.
but is most popular in the colder parts, where the stews are ideal for long, cold nights.

Within the north regional differences are conspicuous. The far northwest relies heavily on lamb, large baked breads, and onions. Shaanxi eats relatively straightforward, less-complex dishes. Beijing is, naturally, a center of major sophistication, with a huge range of local specialties. These include the famous Beijing duck, for which ducks used to be raised specially, with their feeding and care specified from hatching onward. A more recent, world-popular creation is Mongolian barbecue, which is neither Mongolian nor a barbecue but rather a Beijing creation that involves stir-frying meat on a grill with the usual flavorings. Further southeast Shandong has an ancient cuisine more influenced by its locally fertile soil and its long coastline; more fruits, vegetables, and seafood are available.

**SOUTHERN CUISINES IN GENERAL**

From the Yangzi Valley southward rice is overwhelmingly dominant as the staple food. It provided 90 percent of calories in the far south until the last generation. It still provides about two-thirds of grain calories in China. Rice was domesticated in or near the Yangzi Valley; farmers have grown it there for at least ten thousand years. Maize and root crops are far behind. The south has a wide variety of vegetables and fruits. It is much wetter than the north, with many rivers and lakes, and it has a long coastline; thus, fish and other aquatic foods—ranging from frogs to jellyfish—have always been extremely important, providing most of the animal protein wherever people live near water. Elsewhere, animal protein is almost entirely pork, chicken, and duck.

Major ingredients are thus fairly standard across the south. Dividing up the two great regions according to actual cooking styles is more controversial. Some authorities recognize four regions by keeping the north as one but dividing the south into west, far south, and east. Others recognize five (the north split into northwest and northeast), others eight, and still others see all of China’s historic “eighteen provinces” as having unique cuisines. The conservative position is taken here: Four are recognized, with some major subdivisions noted.

**THE WEST**

Classic west Chinese cuisine apparently developed largely in Hunan and spread through Sichuan, Yunnan, and Guizhou. This is famous as China’s truly spicy cuisine. In ancient times hotness came from herbs such as smartweed (*Polygonum* spp.), white and other peppers, and Chinese brown “pepper,” actually the small fruits of a citrus relative (*Zanthoxylum* spp., used quite widely in China and Southeast Asia but primarily in west China). With the coming of New World food crops, chilis appeared and were soon recognized as the ultimate in *la* (piquancy, “hot” spiciness). Sichuan and Hunan food has
toned down in recent years, but formerly some Sichuan dishes contained more chilis than meat, and sometimes almost half the dish was chilis. A range of extremely hot seasoning pastes, made with chilis, fermented beans, and flour, adds yet more to the diet. More common here than elsewhere in China is “aged peel,” which is dried tangerine peel that imparts a powerful citrus perfume to the food; it is considered to have important medicinal value.

Hunan and Sichuan are far inland, with access to river fish but not much seafood, so they tend to focus more on meat, bean curd, mushrooms, bamboo shoots, and forest products. Sichuan is mountainous and draws heavily on montane (relating to the biogeographic zone of relatively moist cool upland slopes below timberline dominated by large coniferous trees) mushrooms and greens. Yunnan has a simpler cuisine with heavy use of beans and noodles.

Yunnan hams are famous throughout China; they are similar to salt-cured mountain hams from elsewhere in the world (Virginia, Spain, Switzerland).

THE FAR SOUTH

China’s far southeast consists of Guangxi Zhuang Autonomous Region and Guangdong Province; Guangdong’s capital, Guangzhou, is the center of China’s most complex and elaborate Cuisine, the Cantonese. There is a Chinese proverb that Cantonese “eat everything with legs except a table, everything that swims except a submarine, and everything that flies except an airplane.” This is exaggerated, but hundreds of species are common in markets, and a small neighborhood restaurant is likely to have over four hundred dishes on the menu. Summary is

A Chinese proverb reflects the diversity of Cantonese cuisine, which caters to those willing to eat “everything with legs except a table, everything that swims except a submarine, and everything that flies except an airplane.” Before cooking, these fish were kept alive in clean water. PHOTO BY JOAN LEBOLD COHEN.
impossible, but some distinctive flavors give coherence to the cuisine. Foremost of these are fermented soybeans that turn black in the fermentation process; they have a unique, meaty flavor especially valued with strongly flavored meats and fish. Fast cooking at high heat is particularly common in the south. Sweet and sour flavors are often combined (but “sweet-sour pork” is generally a sad travesty of true Cantonese sweet-sour dishes). Cantonese food depends on extreme freshness and quality of ingredients. Fish are kept alive—ideally in clean water—until needed. Chickens and pigeons get special feed and care. Vegetables are picked when young and tender, not when full-grown and woody.

The urban cooking of Guangzhou is sophisticated and innovative. Simpler but highly quality-conscious and distinctive variants of southern cuisine flourish in Guangxi Province and in isolated parts of Guangdong, such as the Taishan area.

Cantonese have always tended to migrate from China to find a living elsewhere, and thus Cantonese food has spread worldwide. Simple rural forms of it are ancestral to the “Chinese food” familiar from Peru to England and from Italy to Canada. It has not always traveled well, and naive audiences can be subjected to dishes in which Cantonese ideals of freshness and quality are lost and cheaper ingredients are vastly increased relative to expensive ones. However, many gourmet restaurants in major cities around the world now provide Cantonese and other Chinese foods equivalent to those in the homeland.

Minority Cuisines

China’s minority peoples have distinctive cuisines of their own. Most of those in south and southeast China now eat more or less as their Cantonese and Mandarin neighbors do, although some exotic items such as water bugs may persist. In Yunnan, China’s most diverse province with over thirty minority peoples, specialties range from maize and chilis to the “boneless pig,” a method of storing lard—the meat and bones are carefully removed, the lard salted, and the hide sewed back up. The lard cures in the high mountain air. Some Yi peoples of Yunnan and Sichuan lived until recently on maize and buckwheat; one group, the Nuosu, were famous for their large buckwheat cakes. Rice is now available and more popular.

Tibetan food traditionally was based on roasted barley ground to flour (tsamba) and often beaten up in tea with yak butter. More elaborate foods, including pork, vegetables, and dumplings similar to jiaozi, have tended to replace this diet recently.

More distinctive, with links westward, is the cuisine of China’s far west, the huge province of Xinjiang. Until recently most of the population spoke Turkic languages and ate foods typical of central Asia and the Iranian world. Rice was often cooked as pilaf—stir-fried before boiling, purely a west Asian style. (Chinese fried rice is boiled, dried, and then stir-fried.) Bread is similar to Persian bread and is often a staple. Lamb or mutton is the major meat. Fruit, including apricots, melons, and grapes, is much more important than it is eastward; pilafs often include apricots or raisins. Spicing is sparse or may be influenced by west Asian cuisine (coriander, cumin, cinnamon); absent are the distinctive Chinese flavorings such as soy sauce, brown pepper, and Chinese “wine.” Noodle
dishes and dumplings, similar in appearance to Chinese counterparts, thus taste very different.

Mongolia borders China on the northwest, and Inner Mongolia is Chinese territory. Mongol peoples have become a minority here; 90 percent of the population is now Han Chinese. However, Mongol food survives in remote areas. It is based on small amounts of grain with a great deal of dairy products, usually fermented or made into cheeses. Fermented mare’s milk (kumiss) is popular. (Other milks do not have enough sugar to ferment, unless sugar is added, which was impractical in the old days when sugar was expensive and hard to get.) Mutton is the usual meat. Until recently wild products—game, wild greens, mushrooms, roots—were important, but these are now depleted.

Recent Changes

Chinese food has changed rapidly with the coming of affluence. Change began in Hong Kong and Taiwan in the 1950s and in mainland China in the 1970s and 1980s. East Asia’s economic “miracle” brought meat, tea, wine, sugar, and even more exotic items such as game and rare fungi into almost everyone’s reach. This released a great deal of consumption, partly because of years of “deferred gratification,” partly because food is crucially important in every aspect of social life from festivals and reunions to marriages and business deals.

Also, foods have come from around the world, and American muscovy ducks are as familiar and localized as native Chinese delicacies. Chinese diners are adopting—and adapting—yogurt, hamburgers, and pizza.

Today the Chinese diet is more varied and vitamin-rich but disturbingly high in fat, refined sugar, highly milled grain products, and—for many—alcohol. This trend has had a predictably negative effect on health; deficiency diseases have been replaced by diabetes and heart disease. The future will probably bring balance. The still-inadequate diets of the rural poor will improve, while the affluent will modify their tastes in the direction of simpler, lower-calorie, higher-quality food.

Further Reading

In early medieval China the cult of Maitreya was an important focus of Buddhist belief. The cult originally was associated with the goal of monk-scholars to be reborn in “Tusita heaven” and to hear the dharma directly from the future Buddha Maitreya.

The cult of Maitreya (Mile) in China originally was associated with the vows of monk-scholars to be reborn in what they called “Tusita heaven.” Their goal was to hear the dharma (divine law) directly from the mouth of the future Buddha Maitreya and thus attain Buddhahood. These elite monk-scholars and the royalty and aristocrats who patronized them commissioned images of Maitreya, both sitting and standing in meditation, as objects of worship and as aids for contemplation and visualization. Images of Maitreya standing were indicative of his preaching in Ketumati (generally thought to be modern Varanasi, India) and images of Maitreya sitting were indicative of his waiting in Tusita. The styles were closely connected in the art of the North and South Dynasties (220–589 CE) and the Tang dynasty (618–907 CE) and show that these two aspects of the cult of Maitreya were related in early medieval China.

The beginnings of the monastic aspect of the cult of Maitreya in China can be traced to the exegete (relating to exposition) Daoan (312–385), whose worship was focused on his desire to be reborn in Tusita heaven in the presence of Maitreya so that Daoan’s doubts about the scriptures could be resolved. The Buddhist pilgrim Xuanzang (Hsuan-tsang, c. 596–664) was a devout devotee of Maitreya who wished to be reborn in Tusita, thus the cult became closely associated with his school of Chinese Yogacara.

In early medieval China the cult of Maitreya was an important focus of Buddhist belief. Because the sutras (precepts summarizing Vedic teaching) about Maitreya suggested that he would descend from Tusita to being a peaceful Buddhist millennium after years of warfare and the decline of the Buddhist teaching (mofa), worship of Maitreya spread throughout Chinese society. During the chaos that reigned at the end of the Sui dynasty (581–618 CE) and the rise of the Tang dynasty, a few Buddhist monks and laymen justified their rebellions by claiming to be Maitreya, thus drawing upon the beliefs and imagery common to the cult. The Empress Wu Zetian (624–705) later justified her usurpation of the Tang dynasty throne by identifying herself with Maitreya. Throughout the Song dynasty (960–1279) followers of Maitreya rebelled frequently, and rebels drew upon Maitreya cult imagery to lend religious fervor and authority to their rebellions.

The cult of Maitreya and his image have gone through many transformations in Chinese society. He eventually was reinterpreted iconographically, changing from a slim and sleek figure in earlier dynasties to the rotund Budai (Pu-tai) of the Song dynasty. The “Laughing Buddha,” as he is commonly known, spread throughout Chinese popular culture during the late imperial period (1368–1912).
It is a staple image of traditional Chinese culture that has been exported to the West through immigrant Chinese.

Cultural Revolution
Wénhuà Dà Gémìng 文化大革命

A mass movement occurring during the final decade of Mao Zedong's life from 1966 onward, the Cultural Revolution caused massive political, social, and cultural disruption, and saw an onslaught on the rule of the Communist Party by rebellious groups and radicals. For the central government, the main issue was who was to succeed Mao Zedong as leader of China after his death. This was not resolved during his lifetime.

The Cultural Revolution (CR), officially known as the "Great Proletarian Cultural Revolution," was a complex political-social movement that occurred in China during the last decade of Communist Party-leader Mao Zedong’s life from 1966 onward. Indeed, it is almost certain that without Mao Zedong the movement would never have taken place. It was evidence of Mao’s increasing radicalism in the final stages of his life, showing him subverting the very institutions and structures he had created after the founding of the People's Republic of China (PRC) in 1949 in order to achieve ambitious utopian political goals.

While limited in its economic impact, the CR was to have devastating social consequences, resulting in injury and death to many hundreds of thousands of people and traumatizing large parts of the urban Chinese population such that, in the words of the writer Ba Jin, it might be remembered as China’s "spiritual holocaust." Despite the word Cultural in its title, the revolution was a period during which literary and artistic production was ruthlessly repressed (only eight model operas were recognized and performed during the CR, and novel production ground to a halt). Universities were effectively closed for the first five years, and many prominent intellectuals were sent to the countryside to what were called "May Seventh Cadre schools," named after the date of the edict from the central government that established them. These schools were effectively concentration camps. The great Chinese writer Yang Jiang was to write about the grim, reductive experience of intellectuals in these camps in her book A Cadre School Life — Six Chapters.

One way of understanding the CR in PRC history is to see it as the culmination of several battles that Mao had fought with intellectuals since becoming leader of the Communist Party in the 1930s. In the revolutionary base of Yan'an (a city in Sichuan Province) during the 1940s and then in the early 1950s during the “Five Antis” campaign, Mao had instigated purges of writers, economists, and political scientists. The Hundred Flowers movement of 1957, in which people had been encouraged to voice criticisms of the government’s performance, had brought a deluge of negative feeling, which Mao had responded to by a much greater purge and which in many ways confirmed his suspicions that, within the classes of Chinese society, the intellectuals were among the least reliable. However, larger political issues, inside and outside China, contributed to the CR and made the movement what it was. These issues were:
tensions with the Soviet Union from the late 1950s onward after Premier Nikita Khrushchev’s denunciation of Soviet leader Joseph Stalin, a denunciation with which Mao profoundly disagreed, leading to the withdrawal of Soviet expertise and aid by 1961 and rising military tensions;

2 deep disagreements in the top leadership over the role of economic reform and the need to open up the Chinese economy and engage with the West; and

3 unresolved historical tensions between groups within China, ranging from the People’s Liberation Army (PLA) to those who had been rehabilitated in the 1950s but were still suspect because of the positions they had taken when the Communists were coming to power in the 1930s and 1940s. This situation created a devastating, complex mixture of outcomes that reached its culmination in the years after 1967.

The first signs of the CR came in 1965 from an unexpected direction. By this time Mao Zedong had effectively withdrawn from frontline day-to-day politics after criticisms at the Lushun forum in 1959 about the tragic impact of the Great Leap Forward (Mao’s campaign to quickly catch up with Great Britain and the United States in agriculture and industry). President Liu Shaoqi and General Secretary of the Chinese Communist Party Deng Xiaoping were in charge and had started initial economic reforms allowing greater freedom to farmers in 1964. In 1965 the Shanghai-based writer Yao Wenyuan wrote an attack
on a play, *Hai Rui Dismissed from Office*, written by Beijing vice mayor and Ming scholar Wu Han. In his attack Yao claimed that Wu Han’s play—about the Ming dynasty scholar and official Hai Rui and his unfair dismissal by the emperor—had been an allegorical reference to Mao Zedong’s dismissal of Peng Dehuai, former defense minister, who had been one of the most outspoken critics of Mao at the Lushun forum. This attack clearly had come with some sanction from Mao himself. There was also a clear link to the newly politically active wife of Mao, Jiang Qing, an actress in 1930s Shanghai, who had harbored political aspirations for a number of years but had to repress them on orders from the party. After 1966 she came into her own. The first major victims of the CR began to fall in 1966, among them Beijing mayor Peng Zhen. However, institutionally the movement began with establishment of the Cultural Revolutionary Group as a result of the Sixteenth May Circular, an order issued by the Central Committee of the Communist Party. The group reported directly to the standing committee and was a clear sign that parallel power structures were now directly competing with, and openly confronting, party structures.

**Revisionist Road**

After this development events happened rapidly. On 25 May 1966 Nie Yuanzi, an academic in the philosophy
department at Beijing University, posted a big-character poster (a political poster with large Chinese characters) in which she demanded that people “defend the centre, defend Mao Zedong, and defend the dictatorship of the Proletariat,” which launched an all-out attack on those in the party taking the revisionist road. These sentiments were echoed on 16 August when the “16 Point Decision on the CR” was issued by the central government, threatening to “overthrow those in authority taking the capitalist road.” At the end of 1966 eight large rallies were held in Tiananmen Square in Beijing in which Mao appeared before a radicalized new audience, many members of whom belonged to the newly formed and initially informal “Red Guard” rebellious groups.

On one level the CR can be seen as a power struggle between members of the top leadership in Beijing. It had little impact on the vast majority of the Chinese population, who still lived in the countryside (about 80 percent of China’s population then). Mao saw his greatest threat coming from people around Liu Shaoqi, who had been experimenting with new, more flexible economic ideas and had drifted away from adherence to Maoism with its stress on class struggle. Naturally Mao looked toward the PLA, one of his main sources of power, and to its leader, Marshal Lin Biao, who was a hero of the struggle against the Japanese and of the civil war in the 1930s and 1940s but who had kept a low profile until 1964. In the early 1960s Lin had authorized the collection of key sayings by Mao in a booklet (what was to be named in the West, famously, the “Little Red Book,” although its formal title in Chinese translates as “Quotations from Chairman Mao”). The “Little Red Book” was to become one of the key props of the CR movement, with over 800 million copies printed. Lin Biao was Mao’s key partner in the opening part of the CR, ensuring that the army was Mao’s most dependable ally.

In January 1967 the CR further intensified with CR groups in Shanghai, seizing power from the local party committee. This tussle was representative of the tensions between the new CR organs and the traditional party organs that had been the main holders of power until then. CR committees were organized in cities throughout China, and in Beijing the central CR committee became one of the major decision-making bodies, with members such as Jiang Qing, the sinister Kang Sheng (Mao’s head of secret security), and the Shanghai radicals Zhang Chunqiao and Yao Wenyuan. By February 1967, after the establishment of a “Paris Commune model” in Shanghai, key figures within the party issued open attacks on what they saw as the excesses of the CR. They expressed dismay at the increasing disorder in China’s urban centers and at the violence that had started to be vented toward groups in China’s population. In the most representative event of this period, the Wuhan Incident in central China on 20 July 1967, radical factions in the city clashed, causing the army to intervene and the central government to send in leaders. In the second half of 1967 the CR made increasingly open attacks on Liu Shaoqi and Deng Xiaoping, who were labeled initially the “Numbers One and Two in the Party taking the capitalist road” but who were then openly attacked by name and dismissed from their party posts in December 1967. Liu was to die tragically in Kaifeng, Henan Province, reportedly of untreated cancer, in 1969, although he was posthumously rehabilitated in 1980, four years after Mao’s death. Other figures such as Peng Dehuai were to receive similar violent treatment, being paraded through the streets of Beijing and publicly humiliated and attacked dozens of times throughout the summer and autumn of 1967. Such violence fanned out to the provinces. In Sichuan Province, radical rebellious groups struggled against the party secretary. A similar thing happened in Heilongjiang in the northeast.

**Violence Peaks**

The violence peaked in 1968. Events in Inner Mongolia can be seen as representative of this violence, with the local party secretary, the ethnic Mongolian Ulanfu, being dismissed and removed to Beijing for his safely in mid-1967 and replaced by General Teng Haiqing, a Han from outside the province. From late 1967 increasingly virulent attacks against what was labeled the “Inner Mongolian People’s Party” led to the deaths of 22,000 people and injuries to over 200,000 people, the vast majority of Mongolian ethnicity. In Xinjiang Muslims were forced to eat pork, all mosques were closed, and violent purges occurred in the party. They were under particular suspicion of harboring separatist sentiments as the region had been an independent country from 1945 to 1949. In Tibet cultural sites, temples, and lamaseries (monasteries of lamas) were attacked, and religious life effectively stopped. It would be an oversimplification to say that the CR was
predominantly a Han movement. Some of the most enthusiastic followers in Tibet and Inner Mongolia were ethnically non-Han. The CR’s call to “root out and smash the old” and create a new world because “without destruction there could be no construction” (two popular slogans at the time) reached out to a large constituency. The “Purify the Ranks” campaign that continued into early 1969 attempted to dig out “class traitors” in most of China’s provinces, in some areas leading to massive skirmishes and even to acts of cannibalism and mass suicide.

Such internal turbulence inevitably affected China internationally, causing the withdrawal of most of its ambassadors abroad (all except one, Huang Hua in Egypt, were recalled to China) and the paralysis of the Ministry of Foreign Affairs in Beijing, which was torn in a struggle between radical officials and the more moderate minister, Chen Yi. The burning of the British mission in Beijing in the summer of 1967 did little to help China’s international image, although this act at least brought China’s leaders to their senses. Premier Zhou Enlai, seen as a moderating influence, was to be instrumental in gaining the release of the British journalist Anthony Grey—who had been taken as a government hostage from 1967 to 1969. Paradoxically, from the end of 1968 onward China clearly was increasingly interested in resuming dialogue with the United States, culminating in the visit of President Richard Nixon in 1972. This development perhaps is easier to understand when seen against the background of the real deterioration of Chinese relations with the USSR, which led to bitter clashes on the northeast border in 1969, resulting in several hundred casualties on both sides and the threat of war.

The period from 1966 to 1969 was the most violent and unpredictable of the whole CR decade. During that decade a new leadership, more dominated by the military, was elevated; Lin Biao’s influence reached its peak; and his rapid and dramatic fall began. The decade was marked at the end by the Ninth Party Congress in Beijing, held in April 1969. Part of the argument at the Congress was about how Lin should be marked as Mao’s heir apparent. A more arcane, but still significant, point was Lin’s attempt to enshrine the recognition of the genius of Mao Zedong Thought (i.e., Maoist doctrine) into the party constitution, an act that Mao resisted, along with the attempt by Lin to name himself president, a position vacant since the fall of Liu Shaoqi. By 1970 Lin’s position had become more precarious, with clear signs that, in the top-level rapprochement with the United States, he had been sidelined. The facts surrounding his fleeing China on a plane and its crashing in the Republic of Mongolia in September 1971 are still unclear. Reports by the Chinese government afterward claimed that Lin and a group around him had been plotting either to assassinate Mao (a plot thwarted by Mao’s earlier-than-expected return to Beijing after a trip around central China) or to flee to south China and set up an independent state in Canton. That Lin chose to head to the USSR for refuge is puzzling and has fueled claims ever since that he was, in fact, murdered on Mao’s orders. The impact of his death bewildered the Chinese people, who were slowly informed by the authorities that the man once hailed as the “closest comrade in arms” and successor to Mao was, in fact, “a renegade, scab, and traitor.”

After 1972 Mao was reduced to relying increasingly on his premier, Zhou Enlai, a man who himself was ill with cancer and reportedly had suffered heart problems during the late 1960s. The group that came to be known as the “Gang of Four,” centered around Mao’s wife, Jiang Qing, was a constant source of radicalization within politics during this period. The group was instrumental in launching highly indirect campaigns to attack Zhou and, upon his surprise rehabilitation in 1974, Deng Xiaoping. However, the gang was increasingly loathed within the party, and as Mao grew weaker and less active, groups within the party actively opposed what they saw as the gang’s pernicious influence. The gang still had enough clout, however, to cause Deng Xiaoping to be removed from his position as vice premier in 1976 on the grounds that he was a “reactionary” and opposed to the “correct line.” The death of Zhou Enlai in early 1976, with the attempt to conduct his funeral in private, proved to be the last straw. The Qingming festival in April 1976 was dominated by popular protests and attempts to lay wreaths in memory of Zhou, along with increasing demands that Deng Xiaoping be returned to power. The Tangshan earthquake in the summer, which resulted in over a quarter million deaths, was seen popularly as the augur that a period of Chinese history was coming to a close. On 9 September 1976 Mao Zedong died at the age of eighty-three. His death effectively marked the end of his revolution and of the CR.
Legacy Debated

Mao was to claim, toward the end of his life, that his two greatest achievements had been the Cultural Revolution and the defeats of the Japanese and the Nationalists, respectively, in the Sino-Japanese War (1937 to 1945) and the Civil War (1945 to 1949). He argued that the CR should be repeated every few decades. He told foreign visitors that his attempt to radically change Chinese society had been sincere, although he had evidently failed. The weight of history had been too great. Throwing off feudalism, attacking bureaucratism, and reining in the party were all widely appreciated as worthy objectives and made the CR, at least at its start, a genuinely popular movement, even though it is largely condemned in hindsight. Some writers, such as the Australian-based academic Mobo Gao, argue eloquently that the CR brought major gains to Chinese society, challenging and denting its conservatism, empowering disenfranchised people, and creating genuine equality. They point to the huge imbalances in the Chinese population now and refer back to that period with something approaching nostalgia.

One could argue that the CR was a bitter medicine—a painful process of national self-discovery that needed to be endured for China to get to where it is today. Even so, the price was horribly high, and the Communist Party itself, in its reevaluation of the CR period in 1981, declared that the movement had been a mistake, a calamity that had been visited upon the Chinese people by Mao and the radical leaders around him and that had inflicted the worst damages on the party and country since 1949.
The Cultural Revolution certainly framed the worldview of the people occupying key positions in China now—people such as the current president, Hu Jintao, who had been at Qinghua University in Beijing during the period of the most radical activities in 1966 and 1967, and Bo Xilai, former minister of trade and son of party immortal Bo Yibo, who had been a member of radical groups in the same period. Mao had intended that part of the CR's rationale was to teach young Chinese how to struggle and to understand the importance of politics—to “put politics in command.” In that he succeeded. The CR radicalized and politicized a new generation of Chinese.

The legacy of the movement in China is less easy to summarize. The trial of the Gang of Four in 1981 and the convictions of its members were widely seen as being insignificant because the “fifth member,” Mao Zedong, without whom the others would have had no influence at all, was now dead. The Cultural Revolution remains a sensitive topic in China even today, with many aspects of it little understood. There is, to this day, no openly available Chinese-language account of the period, although one appeared in the 1980s by Yan Jiaqi and Gao Gao but was quickly banned. To some the CR was perhaps the only period in Chinese history when the Chinese were affected by something like mass religious fervor—idolization of Mao reached delirious heights. To others the CR was a period of darkness and suffering. For still others it was a time of liberation. What can be said for certain is that it was a highly complex movement, one that will take many decades to understand and that still influences the superficially very different China of today.

Cunguan

College graduates employed by rural villages have been named *cunguan*, for the Chinese words meaning “village” and “manager.” The program is designed to alleviate high unemployment of urban college graduates and to aid in rural development and sustainability. The *cunguan* program has some features in common with the relocation of urban youth to the countryside during the Cultural Revolution.

*Cunguan* is a new term that describes college graduates who are employed by the Chinese government to help organize villages and provide various services and support to village members. College graduates and the Chinese government have a common interest in the *cunguan* post: the former needs it to secure employment while the latter hopes it will enhance rural community organizations.

**Creation of Cunguan Program**

The *cunguan* program in rural China is designed to meet two needs in Chinese society. First, tens of thousands of recent Chinese college graduates have failed to find a suitable job in urban China. This is a result of the expansion of China’s higher education sector since 1999, creating more graduates, and China’s economic downturn that began in 2008, creating fewer jobs. This job scarcity affects not just the college graduates, but their parents as well. Parents have invested in their children’s education; with no social security as a safety net, they depend on their children to support them in their old age. Many college graduates have to take low-paying or unskilled work to avoid unemployment. A three-year contract as a *cunguan* can be an attractive alternative: it can provide the post holder with a reasonable salary in a government job, recognized work experience, and potentially a leg up for future civil service work.

Second, there is a need for new knowledge, skills, and leadership in rural communities to cope with the stagnation and decline of rural economic and social development. As village leaders in China are getting older (most are now over fifty years old), the Chinese government hopes that *cunguan* will bring new momentum and innovative ideas into rural societies. Chinese officials say that having well-educated graduates work at village-level government positions is a Communist Party strategy to implement the “scientific outlook” on development and accelerate the creation of a new socialist countryside.

Jiangsu Province hired the first *cunguan* in 1995. Since then, more and more local authorities have become interested in the program; by 2005, seventeen provincial governments had put it into practice. In 2008, the central government made a decision to recruit over 100,000 *cunguan* nationwide. If the program grows as planned, there could be 600,000 new jobs, one *cunguan* per village, by 2018. Chinese vice president Xi Jinping has said the country urgently needs more grassroots officials who can lead farmers to get rich and make the countryside more stable.
**Cunguan and Zhiqing**

As a national strategy for the career development of young people, the cunguan phenomenon resembles the policy of zhiqing ("reeducated youth") during the Cultural Revolution (1966–1976), when millions of urban graduates from high or middle schools were sent to the countryside to work and live with rural residents. Both cunguan and zhiqing provided relief from urban unemployment, and both resulted in migration from urban to rural areas, giving the urban youth knowledge and experience of rural life.

Although both programs were described as ways to “drive socialism,” there are many differences between the two programs. Cunguan are expected to help with rural development: Their knowledge and education should benefit rural communities through regulation and policy dissemination, project planning, community information, agricultural extension, or public relations, for example. The cunguan program is voluntary and often highly competitive; it is an alternative to unemployment or poor-paying, menial urban jobs. Cunguan are rewarded: They are paid a salary; other expected benefits may be the chance to be recruited or promoted as civil servants later or a residence permit for an urban area. In any case, they may make the choice to leave the countryside after their contract ends. Zhiqing, on the other hand, were expected to learn from the rural populace by doing rural work; their formal education was a detriment, not a plus. Zhiqing were often forced to relocate; neither they nor their parents had a choice. They were certainly not paid by the government, but were expected to earn a basic living working beside village natives. Zhiqing had little chance of promotion or leaving the countryside.

**Outlook**

Opinions differ as to the lasting value of the cunguan program. Supporters of the government policy say it provides a unique opportunity for college graduates to gain life experience and learn about the complexity of the rural reality. Those in favor also believe graduates with cunguan experience will have greater chances for career development than those without it. Villages, especially poorer ones, are optimistic that the cunguans will help them. For example, Internet-savvy grads can help promote village products to online customers. Others, however, have doubts about the effectiveness of the program. It is very difficult for cunguan to gain the trust of rural residents unless they can prove their commitment to village members. Some village leaders, proud of their village and their work, believe the village needs no further improvement.

It is too early to predict the long term impact of the cunguan program. Cunguan are expected to mediate between local government and village members in order to deliver governmental services. This dual nature of the cunguan post will make it difficult for them to balance the different roles of villager and officer, and different interests and needs of farmers and governments.

China’s currency, the renminbi, is getting stronger with the Chinese economy. It is gaining worldwide attention because it has appreciated greatly due to China’s significant trade surplus, foreign reserves, and other factors. Whether the value of the renminbi will continue to grow or fluctuate are questions catching Chinese and others’ ears.

The renminbi is the monetary currency of the People’s Republic of China, with RMB or CNY (China yuan) as its abbreviation and ¥ or 元 as its symbol.

Since the founding in 1948 of Renmin Bank of China (the central bank of China), which is in charge of issuing, printing, and managing renminbi, five editions of renminbi have been issued: 1948, 1955, 1962, 1987, and 1999, with the fifth edition and part of the fourth edition still in circulation. Each edition has a theme, such as agricultural and industrial development for edition three and harmonious development involving economy, culture, and environment for edition five. Denominations of renminbi are 1, 2, and 5 cents, 10, 20, and 50 cents, and 1, 2, 5, 10, 20, 50, and 100 yuan (1, 2, 5, 10, and 50 cents and 1 yuan are coins, and other denominations are paper).

The renminbi has experienced several exchange rate fluctuations in the past half century. From 1949 to 1952, when the renminbi was first issued as China’s legal currency, a floating exchange rate was used. From 1953 to 1973 the renminbi was officially tied to the U.S. dollar at 1:¥2.46. At the same time China operated a planned (government regulated, as opposed to a market) economy, so the exchange rate did not make much difference because little foreign trade went on between China and other countries. In 1973 the first oil crisis broke out, together with worldwide inflation and fluctuations in exchange rates. Most Western countries adopted a floating exchange rate. China at this time started to connect the renminbi to a basket of currencies rather than just the U.S. dollar to avoid instability caused by fluctuations in the dollar’s exchange rate. The exchange rate between the

Illustration of a coin from a treasure hidden at Xiangyang during the siege in 1268-73.
U.S. dollar and the renminbi was gradually adjusted to $1:¥1.50, which was 39.2 percent appreciation for renminbi until 1980.

From 1980 to 1994, when China started its open-door policies and China's economy and foreign trade grew rapidly, a dual exchange rate was adopted: the official exchange rate and the domestic balance price (an exchange rate calculated according to the balance of foreign trade by Chinese companies). During this period the official exchange rate between the U.S. dollar and renminbi fluctuated between $1:¥1.50 and $1:¥5.70, and the domestic balance price fluctuated over a wider range: from $1:¥1.50 to $1:¥8.70 because of rapidly growing foreign trade. From 1994 to 2005 the renminbi was again connected more directly to the U.S. dollar (although not officially), and the exchange rate between the two was allowed to fluctuate only within a narrow range of $1:¥8.27 to $1:¥8.28, with strict regulation.

On 21 July 2005, The People's Bank of China announced that the renminbi, for the second time, was to be connected to a basket of currencies rather than directly to the U.S. dollar, and the exchange rate was changed to $1:¥8.11, a 2 percent appreciation for the renminbi. The daily fluctuating range of the renminbi was doubled from 0.15 percent to 0.3 percent and rose to 0.5 percent on 18 May 2007. From this time the renminbi has continued to appreciate (as of 31 July 2008, the exchange rate between the U.S. dollar and the renminbi was $1:¥6.8205).

The appreciation of the renminbi is a two-edged sword. On one hand, this gradual and steady appreciation can make the formerly overvalued renminbi go back to its real value, which would effectively avoid sharp fluctuations in exchange rates and variations in the national economy. Meanwhile, China's foreign surplus will decrease, and its consuming power will be greatly
in this respect China’s production will be strongly stimulated. On the other hand, with a higher “international price,” many of China’s exporters are losing their competitive edge because they are increasingly unable to offer low prices, the basis of their competitiveness. In addition, uncertain factors, such as unemployment, domestic inflation, and currency speculation, are emerging.

Managing a currency is key to establishing a stable economy, but such management remains a challenge for China and the rest of the world, since all currencies in today’s global market are interconnected.

Zhao Daping. (2007). Renminbi hui lv bian dui Zhongguo wai mao de ying xiang [The impact of renminbi exchange rate on China’s trade balance]. Shanghai: Shanghai People’s Publisher.
Some foreign critics, especially in the United States, have claimed that China has manipulated the value of its currency, keeping the yuan at an artificially low rate and not allowing proper market functions to operate.

The valuation of the Chinese yuan (or renminbi) has become a highly sensitive and politicized issue between China and the United States and, perhaps less pointedly, between China and the European Union. Since China’s entry into the World Trade Organization in 2001, China has run increasingly large trade surpluses with both of these trading partners. The prominence (and symbolism) of these deficits has become something of a battleground between those who believe the prominence represents a deliberate policy to distort and control world trade patterns in China’s favor and those who believe that the prominence is a natural outcome of globalization, and that to argue against China embracing this prominence, after so many years when it was criticized for holding itself apart, seems contradictory.

Criticism of the potential manipulation began to surface in the late 1990s, but with the accrual of massive amounts of foreign reserves by the Chinese central bank from 2001 onward, these criticisms became more focused and politically problematic. In early 2006 China overtook Japan as the holder of the world’s largest foreign exchanges. It had achieved this ranking through almost twenty-five years of exports and over $700 billion of foreign investment coming into China. Becoming one of the world’s most open economies was achieved while the central government still maintained two important levers of economic control. It maintained the nonconvertibility of the Chinese currency, and it exercised, largely through the State Administration for Foreign Exchange (SAFE), tight controls over capital outflows. Those purchasing goods in China (Wal-Mart or Tesco, for instance) for export to overseas markets had to pay in dollars, euros, or another convertible currency, and this money went into the central bank. The supplier was finally paid in local currency. Those Chinese companies that wished to invest or purchase abroad had to apply to the Bank of China—or, for large amounts, SAFE—for foreign currency to do this. There is, therefore, a wall between Chinese currency and foreign currencies. The Chinese government defends this wall by pointing out that without it the Asian economic crisis in 1998 would have ravaged the Chinese economy as much as those of Indonesia and Malaysia.

The value of Chinese yuan and the U.S. dollar have been pegged for a number of years, although partly because of U.S. pressure and partly because of China’s entry into the World Trade Organization and increasing internationalization of the Chinese economy, the exchange rate has been given some room to move within a tightly regulated value range. As the trade deficit with the United States in particular increased dramatically, particularly after 2003, there were complaints among U.S. policymakers and manufacturers that the Chinese yuan was being held at an artificially low rate and that the Chinese government was not allowing proper market functions to operate. The claimed degree of undervaluation varied from 15 percent to 40 percent.
An undervalued Chinese yuan would give Chinese manufacturers an unfair advantage because it would mean that they were able to export their goods at a much cheaper price than local producers in the destination country. But proving that currency manipulation has been going on has proved difficult. The Economist magazine has introduced the “Big Mac” measure by which the local price of a Big Mac hamburger is used as the benchmark across different kinds of economies and other goods compared with it. On this measure Chinese goods have been claimed to be 20 to 30 percent below value over most of the last twenty years. Even so, this measure has been criticized as crude.

In fact, complex reasons exist for the increase in Chinese exports abroad, some of them internal, some of them external. And although currency values might be an easy target, the story is not so straightforward. China has generally controlled the factors of production (the factors that contribute to the making of goods, such as electricity, labor, land for factories, human labor costs) strictly in the last quarter of a century. In that sense, China has subsidized the costs of manufacturing, starting to introduce a proper free market similar to ones that exist in developed economies only in the last few years. The costs of borrowing capital and employing people have been kept artificially low until recently. The Chinese government argued that it did this in order to help China build up capacity in a hugely competitive and complex international market. Although some analysts say that the most important advantage China has had in its ascent to becoming the “world’s factory” has been cheap and plentiful labor, this was one among several advantages.

A further contributing factor has been the extreme liberalization of foreign investment regulations into China, meaning that manufacturing in particular has benefited from the opening up of hundreds of thousands of joint ventures and the creation, particularly in south China around the Pearl River delta, of a massive manufacturing and industrial area. China has become such a large and successful exporter because of the benefits it has offered to foreign investors. Its export success, therefore, has also led to advantages and help for foreign partners.

Unique among major economic powers, China maintains this control over its currency. But this means that, especially in a period of economic downturn, it remains a lightning rod for foreign critics and for those who see protectionism as a valid response to international trade competition. This issue is likely to remain as long as China continues with this macroeconomic measure. The real reasons for the deficits, however, are far more complex and would remain in place even were the Chinese yuan to be revalued.

Cyberspace

Diànnǎo kōngjiān 电脑空间

Cyberspace refers to a domain characterized by the use of electronics and the electromagnetic spectrum to store, modify, and exchange data via networked systems and associated physical infrastructures. In China the word Internet is used in lieu of the word cyberspace. By early 2009 the number of Internet users in China increased to 298 million, second only to the number of Internet users in the United States.

The word cyberspace is a combination of the words cybernetics and space. It was created by the sci-fi novelist William Gibson in his short story Burning Chrome published in Omni magazine in 1982 and popularized by his 1984 novel Neuromancer. Today cyberspace is a domain characterized by the use of electronics and the electromagnetic spectrum to store, modify, and exchange data via networked systems and associated physical infrastructures. Because the word cyber itself connotes computerization, digitalization, multidimension, and the like, the word cyberspace does not have a unified Chinese transliteration and is usually translated as “Saibo space” or is called “network space” or “virtual space.”

Cyberspace in China

In China the word Internet is used in lieu of the word cyberspace; the word cyberspace is seldom used in official documents or unofficial communication. In few Chinese research articles about the Internet is the word cyberspace mentioned. According to the China Internet Network Information Center (CNNIC), by the end of 2007 the number of netizens (active participants in the Internet community) in China increased to 210 million, second only to the number in the United States. China’s total is expected to surpass that of the United States in 2008.

The gender breakdown of netizens in China is 57.2 male and 42.8 female; 69 percent of netizens are younger than thirty years of age; 41 percent are older than fifty; 72.2 percent have high school or higher educations; 75 percent live in urban areas and 25 percent in rural areas. In general, the Internet is expanding its influence to people younger than eighteen and older than thirty, to groups with junior middle school and lower educations, to rural residents, and to low-income residents. Regarding location, 67.3 percent of netizens use the Internet at home, 33.9 percent in Internet cafes, and 24.3 percent in the office. The average online time is 16.1 hours a week. Netizens who access the Internet via mobile phones number 50.4 million. Regarding reasons for logging onto the Internet, 66.6 percent use it to get information, 47.9 percent to communicate, 39.2 percent to read news, and 38.4 percent to be entertained. The top seven uses of the Internet are gain access to music, instant messaging, online video, news, search engines, games, and e-mail. Netizen satisfaction with the Internet is not high, just more than 60 percent, and only 33 percent of netizens trust information found on the Internet. Such a lack of trust possibly restrains the further development of the Internet in China.
Functions of Cyberspace in China

During the development of the Internet in China, its functions have been expanded into four aspects: entertainment media, communication tools, information channels, and life assistance.

According to the 21st Report on China Internet Development by the CNNIC, the recreational function of the Internet is utilized on a large scale in China. During a half-year period 86.6 percent of netizens listened to online music; 71.2 percent downloaded audio files; 76.9 percent watched online video; and 40.5 percent downloaded video files. Online games took 59.3 percent of total online recreational time. A netizen on average spent 7.3 hours per week on online games.

For communication Chinese netizens mainly use the Internet for instant messaging and e-mail. In China 56.5 percent of Internet usage is for e-mail, and 81.4 percent of Chinese netizens use instant messaging.

Almost three-quarters of netizens use the Internet as an information-searching engine; a similar number use it to read news, and one-quarter have their own blog. Consequently, cyberspace changes the habits of Chinese people as they gather and absorb information, especially breaking news and investigative news reporting. Cyberspace is also a place to foster public communication and put forth efforts to build a civil society. Cyberspace is widening and deepening the process of China’s informationalization and globalization. Internet job-seeking, Internet education, Internet shopping, and Internet banking and stock brokerage make up the main part of life assistance for netizens.

Internet Supervision

To supervise use of the Internet in China the central government has established rules, including Regulations on the Protection of the Right of Communication through Information Network (2006), which clearly define the rights of citizens, businesses, and social groups to communicate information through the Internet.

In addition, regulations on domain name supervision and Internet security have been implemented. The most distinguishing feature of the regulations is strengthening supervision over Internet news and the content of information, bringing them into the orbit of legal management and therefore ending the previous disorder in Internet news and communication. At the Seventeenth National Congress of the Communist Party of China in 2007 the Central Committee proposed the slogan “Cultural Prosperity” and guidelines for promoting the development of Internet media and Internet industrialization.

The principles of the Chinese government on supervising the Internet are as follows: develop the Internet actively and use it fully, strengthen supervision, promote its benefits, abolish its harm, and bring its advantages into full play. The government has passed a series of laws on Internet supervision since the middle and late 1990s. During the Seventeenth National Representative Conference of the Chinese Communist Party (15–22 October 2007), the Central Committee of the party promoted the policy of thriving culture, which contains guidelines on developing Internet media and Internet industries. One can safely predict that the Internet will continue to have a profound influence on China.

The Dalai Lama is the spiritual and temporal leader of Tibetan Buddhists. The present Dalai Lama, Tenzin Gyatso, is the fourteenth in a line of succession. He leads a Tibetan government-in-exile in India and is a spokesman for nonviolence and Buddhist ideals.

The Dalai Lama is the temporal and spiritual leader of the Tibetan Buddhist people, who regard him as the earthly manifestation of Chenrezi, the bodhisattva (incarnating deity) of compassion. Each Dalai Lama is regarded as the reincarnation of his predecessor, and after a Dalai Lama dies, a search is conducted for the young boy in whom the Dalai Lama is considered to have been reborn. The present Dalai Lama, Tenzin Gyatso (b. 1935), is the fourteenth in a line of succession that originated in a fourteenth-century disciple of the founder of the Gelugpa sect, the leading school of Tibetan Buddhism.

The fourteenth Dalai Lama, commonly referred to in English by the title “His Holiness,” was born into a peasant family in the village of Takster in northeastern Amdo Province of Tibet (now part of China’s Qinghai Province). His predecessor had “passed to the heavenly fields” in 1933, and in 1937 Tenzin Gyatso was recognized as his reincarnation. Tenzin Gyatso was taken to Lhasa, the capital of Tibet, in 1939 and in February 1940 was enthroned in the Potala Palace. While a regent ruled Tibet in his name, Tenzin Gyatso began the course of studies that culminated in his being awarded the Lharampa Geshe degree (roughly equivalent to a doctorate in Buddhist studies) in 1959.

Because of the crisis caused by Communist China’s invasion of Tibet in October 1950, Tenzin Gyatso, then...
sixteen years old, assumed temporal power in Tibet on 17 November 1950. He remained there under Chinese authority until the activities of the Communist regime prompted him to flee Lhasa in March 1959. Although he was pursued by Chinese forces, he reached India. There, with about one hundred thousand of his followers, the Dalai Lama established a Tibetan government-in-exile in Dharamsala in the Himalayan foothills of northern India. He has since become the primary ambassador of the Tibetan exile movement as well as a spokesman for nonviolence and for the Buddhist ideal of universal compassion. In October 1989 he won the Nobel Peace Prize.

A charming and modest man with a great appeal in the West, the fourteenth Dalai Lama prefers to be known as “a simple Buddhist monk.” He remains the focus of Tibetan identity in the world. His leadership has been characterized by an openness to change, a steadfast belief in the principles of nonviolence, and the promotion of dialogue between religions and science.

Since 1959 the Chinese have argued that the Dalai Lama is a “tool of Western imperialism,” working against the Chinese Communist state. They claim his demands for Tibetan autonomy mask the desire for Tibetan independence—and thus portray him as a threat to the unity of China. Talks between representatives of China and the Dalai Lama have been held on occasions, most recently in 2008, but have always ended without any measurable progress being made. With the present Dalai Lama now seventy-five years old and subject to bouts of ill-health, the question of his next incarnation arises. The Dalai Lama has stated that his next incarnation will not appear in China, but as it has done in the case of other important Tibetan Buddhist incarnations, the Chinese

**Dalai Lama on Living in Exile**

_In his autobiography published in 1990, the Dalai Lama relates first hand his feelings on being exiled from his homeland of Tibet, and recalls his former life there._

I fled Tibet on 31 March 1959. Since then I have lived in exile in India. During the period 1949–50, the People’s Republic of China sent an army to invade my country. For almost a decade I remained as political as well as spiritual leader of my people and tried to re-establish peaceful relations between our two nations. But the task proved impossible, I came to the unhappy conclusion that I could serve my people better from outside.

When I look back to the time when Tibet was still a free country, I realize that those were the best years of my life. Today I am definitely happy, but inevitably the existence I now lead is very different from the one I was brought up to. And although there is clearly no use indulging in feelings of nostalgia, still I cannot help feeling sad whenever I think of the past. It reminds me of the terrible suffering of my people. The old Tibet was not perfect. Yet, it is true to say that our way of life was something quite remarkable. Certainly there was much that was worth preserving that is now lost forever.

...Of course, whilst I lived in Tibet, being Dalai Lama meant a great deal. It meant that I lived a life far removed from the toil and discomfort of the vast majority of my people. Everywhere I went, I was accompanied by a retinue of servants. I was surrounded by government ministers and advisors clad in sumptuous silk robes, men drawn from the most exalted and aristocratic families in the land. My daily companions were brilliant scholars and highly realized religious adepts. And every time I left the Potala, the magnificent, 1,000-chambered winter palace of the Dalai Lamas, I was escorted by a procession of hundreds of people. Invariably almost the entire population of Lhasa, the capital, came to try to catch a glimpse of me whenever I went out. There was an awed silence and often there were tears as people lowered their heads or prostrated themselves on the ground when I passed.

state will oversee the search for a new Dalai Lama among the Tibetan Buddhist population of China. Thus two candidates will compete for popular acceptance as the next Dalai Lama.

Dalian

Dàlián 大连

6.2 million est. 2007 pop.

Perched at the tip of the Liaodong Peninsula on China’s northeast coast, the city of Dalian has undergone many changes through the years. It became a major seaport during the Ming dynasty (1368–1644) and has since been occupied by the British, the Russians, and the Japanese. Today it is both a popular and thriving tourist destination in Liaoning Province and China’s largest oil and gas port.

In many ways the history of Dalian (urban area 12,574 square kilometers) and its adjacent district of Lushunkou (Port Arthur) represents the tumultuous history of most of coastal China over the last 150 years—from dynastic decline and colonial occupation during the Qing dynasty (1644–1912) to Cold War stagnation under Chinese Communist Party leader Mao Zedong (1949–1976) and finally to economic resurgence under the policies introduced by party leader Deng Xiaoping in 1978.

The site has been populated for more than two thousand years, but its mention in dynastic records as a major seaport during the Ming dynasty (1368–1644) really begins the modern era. Since then the city’s excellent natural harbor and strategic coastal location as the “Gateway to Manchuria” have brought both tragedy and prosperity. Incomes and per capita gross domestic product (GDP) are some of the highest in China due to a fortuitous location for trade with China’s increasingly important northeast Asian neighbors—Japan, South Korea, and Russia—combined with a diverse and balanced economy.

During the dynastic era the city’s location at the southern tip of the Liaodong Peninsula allowed quick commercial and naval access to the rest of coastal China via the Yellow Sea and the Pacific Ocean. The Chinese were not alone in appreciating this location. Interest in the harbor led to a first brief foreign occupation by the British during the Second Opium War (also called the “Arrow War,” 1856–1860). Returned to the Chinese at the end of the war, the site was rented, under pressure, to the Russian empire (1898–1904) and renamed “Dalny,” only to be lost to Japan as a concession under the Treaty of Portsmouth, which ended the Russo-Japanese War in 1905. Occupation by the Japanese—first directly and later as a portion of the Japanese “puppet state” of Manchukuo—lasted until 1945. Dalian citizens continue to have quite mixed emotions about this era and the Japanese. While
a few historic buildings are all that remain from the Russian era, Japanese influences on the city, then renamed “Dairen,” remain profound. Until post-1978 reform-era investment drastically expanded and modernized infrastructure, much of the city’s industrial infrastructure as well as the port and transportation network must be credited to Japanese occupation-era development. Dairen was the terminus of the rail network that brought iron, coal, and oil from Manchuria to feed the great wartime factories of the Japanese empire. In 1937 Japanese planners rebuilt and expanded the entire city, which was then considered one of the most beautiful in the empire. Of course, everything—the parks, the roads, the railroads, the warehouses, and the port—was built on the backs of Chinese conscripted laborers. At the end of World War II Dalian had one of the highest proportional concentrations of Japanese outside of the home islands. Ironically, the expatriate Japanese population at the present time is also one of the largest among the cities of China.

Before the city was restored to full Chinese sovereignty in 1955, it was jointly governed for a decade by the Russians and Chinese as the city of Luda. Little of note changed until after 1978, when the policies of the reform era and commensurate growth in international trade brought newfound prosperity. Renamed (again) “Dalian” in 1979, it was one of the first fourteen “Open Door” cities selected in 1984 for foreign investment opportunities. The industrial sector remains focused on petrochemical processing, but there is also recent growth in electronics and semiconductors. The city is China’s largest oil/gas port and the country’s third-largest seaport in terms of gross tonnage. It is one of a few Chinese cities that is both an important industrial center and a tourist destination. With a beautiful, rugged coastline, many historic Russian and Japanese buildings, excellent seafood, and more than seventy spacious, landscaped parks, Dalian bases an increasing portion of its economy on tourism.

The *danwei* (unit) was for many years after the creation of the People’s Republic of China the all-inclusive work unit for urban Chinese, encompassing everything from a lifetime social welfare system to a network of work, home, and political relationships. The reforms of the last three decades have considerably weakened the traditional *danwei* system, where the price of security was often a lack of social mobility.

The *danwei* (unit) dominated the workplace in urban China after 1949. At its peak the *danwei* was ubiquitous: Government and party organizations, state-owned enterprises, financial institutions, and educational establishments were all designated as *danwei*. With relatively few exceptions *danwei* employees were entitled to lifetime employment. Typically a *danwei* provided its employees with housing, health care, recreational activities, rationed goods, pensions, and so forth. For many the distinguishing features of a *danwei* were a lifetime social welfare system from cradle to grave and a network of relationships encompassing work, home, neighborhood, and political membership. Thus, many scholars trace the origins of the *danwei* variously to the Communist free-supply system of the 1930s, the heritage of labor protest, and the evolution of labor management institutions.

Still, the *danwei* is best understood as a part of the prevailing administrative system embracing virtually all government, business, and financial, as well as educational institutions in urban China after 1949. Such a definition emphasizes that these institutional entities were integral parts of the overall state administrative structure, a character that cannot be explained by any of the specific traditions or institutions scholars have heretofore examined. The evidence suggests that the origins of the *danwei* in the sense of the prevailing administrative system can be traced to the Nationalist struggle to rationalize the administrative bureaucracy during the War of Resistance against Japan (Second Sino-Japanese War, 1937–1945), when the Nationalists used the term *danwei* to designate political, economic, and administrative organizations. Beginning in the early 1940s the government and state-owned enterprises routinely used the term *danwei* to identify various organizations as well as units within those organizations. Even the term *work unit*, which for decades has been the standard although erroneous transliteration for the term *danwei*, was carefully defined in 1943 and thereafter used regularly in Dadukou Iron and Steel Works (DISW), the largest state-owned enterprise in Nationalist-controlled areas during the war.

These same *danwei* also acquired some of their defining characteristics during the War of Resistance against Japan, including *danwei* provision of social services and welfare. Studies have shown, for example, that during
the war self-contained enterprise-run service and welfare communities were formed. Employees lived in factory apartments and dormitories, bought their daily necessities at factory cooperatives, purchased vegetables grown at factory farms, and went to factory clinics and hospitals for medical treatment. Employees’ children received their education in factory schools. When employees died, they sometimes were buried in factory cemeteries.

To put it differently, the danwei designation of political, economic, and administrative organizations and danwei provision of social services and welfare predates the Communists’ rise to power. After 1949 the danwei became part of urban China’s administrative system, expanded its function as the provider of social services and welfare, and developed new characteristics such as party control, permanent employment, and labor immobility. As a part of the prevailing urban administrative system, a typical danwei had administrative departments or divisions that matched their counterparts in pertinent administrative bureaucracies at a higher level. For example, a typical danwei had a finance department or division that coordinated with the finance department or division of a municipality and ultimately with the ministry of finance of the central government.

Loss of Autonomy

An inevitable consequence of the incorporation of danwei into the overall administrative structure was the loss of autonomy on the part of danwei leaders or managers over issues such as wages and personnel. In addition, a typical danwei offered its employees housing, recreation and health-care facilities, schooling for their children, ration coupons for food, and pensions and burial funds. The danwei also engaged in a variety of political activities under party leadership and supervision, such as political campaigns as they were typically carried out danwei by danwei. In fact, the danwei represented an extension of the Communist Party because the danwei had within it either a party committee or commission, depending on the danwei’s size. Under the party committee or commission were the party secretary’s office, the organization department, the propaganda department, and the discipline inspection department. Such an organizational structure was designed to match the organizational structure of the Communist Party organization at a higher level. Finally, the danwei was characterized by not only permanent employment but also labor immobility. Few employees obtained permission to transfer from one danwei to another.

The reforms initiated by the Communist Party toward the end of the 1970s significantly affected the danwei system. Within the danwei the labor contract has replaced permanent employment as the basis of employment for a majority of employees. Material incentives have replaced ideological and psychological ones in an effort to promote labor productivity. Most danwei no longer provide employees comprehensive social services and welfare. The party-state has relaxed what had been rigid administrative and political controls that various danwei exercised over their employees. Employees can transfer from one danwei to another with relative ease. At the same time, the reforms have permitted development of joint-venture, collective, and privately owned enterprises, which are not extensions of the government apparatus. Within those new enterprises entrepreneurs and managers have introduced practices of scientific management designed to enforce labor discipline and maximize profits, although recent studies suggest that some of the enterprises have reproduced many features of the danwei system.

System Weakened

The reforms of the last three decades have not only weakened the traditional danwei system but also have had profound implications for the reconfiguration of urban Chinese society. In response to the tremendous social and economic changes, including the massive unemployment resulting from the reform and privatization of state-owned enterprise danwei and the presence of millions of migrant workers, the party-state introduced in the 1990s experiments that led to the creation of new urban communities (shequ) under government control and supervision and with jurisdiction over clearly demarcated urban space. The responsibility of those communities was no longer confined to the provision of
social services and welfare; it included functions ranging from social service and welfare provision to culture, health, education, morality, policing, and grassroots democracy. Although the future of those communities is unclear at the dawn of the twenty-first century, it appears that the communities may eventually replace the danwei as the basic social and administrative organization in urban China.

爱屋及乌

Ài wū jí wū
Dao (the Way)

Dao denotes a road, path, or way. Every ancient Chinese thinker interpreted the concept of dao to suit his philosophical system. For the Confucians, dao refers to the way of the early sage kings. For the Daoist, it refers to the way of nature.

Dao (the Way) is one of the most important concepts in Chinese philosophy. Almost every Chinese philosophy employed its own operational definition of dao, which denotes a road or a way. (The character dao is a pictograph representing a head on a path.) Anything that has a consistent course or specific direction is called a dao. Dao is used to connote a process, a method, or an art. In Chinese philosophy dao has two main foci: the dao of nature, or heaven in the Confucian context (tian zhi dao), and the dao of humans (ren zhi dao).

Daoists emphasize the way of nature. They are concerned about living in harmony with the way of nature, believing that social harmony flows spontaneously from nature. They recognize the importance of the human way, the way of the sage ruler, for keeping the community on the path of living in harmony with nature. The way of humans became the focus of Confucianism. Confucians are more concerned about the social norms that promote harmony within the family, community, and state.

Most Primitive Reality

Daoists abstracted the concept of dao, transforming it into the most general concept that simultaneously generates, maintains, and diminishes the universe. Some Daoists, such as Master Lao (Laozi, sixth or fourth century BCE), focus on the dao itself as the most primitive reality from Daoist texts discuss the dao of heaven or nature, but Confucians are more concerned about the social norms that promote harmony within the family, community, and state.

The yin–yang and bagua symbols, both significant to the philosophy of Daoism.
which all things and thoughts unfold. *Dao* was abstracted from nature. For Laozi the *dao* became the empty void from which all things arise and return. *Dao* is the primal unity that generates all diversity, and it is the great diversity of the myriad things that return to undifferentiated unity. Laozi raises the concept of the *dao* to new heights, making it the primordial cosmic force. Consider poem 25 of the *Laozi: Daodejing (Master Lao’s: The Way and Its Power)*:

There is something chaotic and yet completely formed;  
Generated before the heavens and earth.  
Solitary! Silent!  
Standing alone, not changing.  
Pervading all without limit.  
Regard it to be the mother of all under heaven.  
I do not know its name.  
Call it *dao*.  
Compelled to name it.  
Call it great.  
To be great means to pass on.  
To pass on means to go far.  
To go far means to return.  
So it is said, “The *dao* is great.  
The heavens are great.  
The earth is great.  
And the king is also great.”  
Is not the king one of the four great things in the world?  
Humans model the earth.  
The earth models the heavens.  
The heavens model the *dao*.  
The *dao* models its own self. ( modifying Addiss and Lombardo 1993, 25)

The concept *dao* is understood to be an independent, objective reality that begins and returns. The reality of *dao* is unlike anything in this world. As the primordial origin, *dao* is the nexus of undulating opposites. It is empty but generates and fills things. It has no creator and is prior to the supreme ancestor or god (*Laozi*, poem 4). *Dao* is vague and unclear but a reality. It is obscure and dark yet contains the vital source of life (*Laozi*, 21). A person cannot see, hear, or touch it. *Dao* is the shapeless shape, the formless reality (*Laozi*, 14). *Dao* has various modes of operation. It generates the primordial unity (*Laozi*, 42).

It does not engage in any particular activity, yet nothing is left undone (*Laozi*, 37). It operates by returning, and being soft, weak, and flexible; it is useful (*Laozi*, 40). For Laozi the operations of the *dao* are a model for the sage ruler to emulate.

In contrast, Confucians note that the disciples of the philosopher Confucius (551–479 BCE) did not receive instruction concerning the way of heaven (Ames and Rosemont 1998, 5/13). Despite that passage, Confucius believed in the way of heaven and that his life mission was condescended by heaven (Ames and Rosemont 1998, 9/3). Confucius was not a speculative thinker. He was concerned about the decay of the Zhou dynasty (1045–256 BCE) culture. He felt that people were losing the *dao* of the early sage kings, the social norms that bound people together in their extended families, communities, and states.
Proper Way of Life

This pragmatic approach led Confucius and his followers to focus on the proper way for maintaining social and political life. So Confucius said, “Set your intention on the dao, sustain yourself with virtue, rely on human kindness, and relax in the arts” (modifying Ames and Rosemont 1998, 7/6). These are closely linked. The arts refer to ritual and music. Listening to the right music was believed to civilize people. Ritual action was the basic norm for controlling behavior and the correct way to express kindness. For the Confucians kindness or benevolence is the most important virtue. Living in accord with the virtues is the means to put the cultural way of the ancient sage kings into practice. The dao for Confucius was the way of the cultural tradition. It was the way of the founders of the Zhou dynasty, King Wen and the duke of Zhou.

Chinese philosophers employed the term dao to describe their own approach. For example, the dao of Mozi (flourished 479–438 BCE) is the way of promoting social harmony by loving each and every person equally. The dao of Zou Yan (305–240 BCE) is to follow the natural cycles of the five phases, namely, wood, fire, earth, metal, and water. The dao of the militarists is to practice martial arts. The dao of the legalists is to codify laws and standards. For the most part, every philosopher made reference to the way of the ancient sage rulers, the kingly way, and the ways of specific people, such as ministers or craftsmen. Because of these more common expressions, the term dao comes to mean a teaching, a philosophy, or a religion.

The ancient Chinese philosophy known as Daoism is a complex cultural phenomena. Inspired by ancient shamanic breathing practices, Daoism is a philosophy that focuses on self-cultivation and finding value and purpose in this life. It developed into a philosophy of nature, a political philosophy, and a religion. While Daoism changed and developed, it maintained its original position as a way of life.

When people recognize that death finalizes life, they develop a philosophy to construct meaning, value, or self-esteem in the face of death. The problem of death is compounded by two closely related concerns, namely, living in harmony with nature and living in harmony with other people. Confucian philosophy emphasizes the manner in which people could live in harmony with each other. Daoist philosophy emphasizes how people could live in harmony with nature.

Daoism as a philosophy has its roots in ancient shamanic practices of south China. Shamans are known for their ecstatic journeys and visions achieved through altered states of consciousness. Over time shamanic practices were transformed into meditation and breath-control techniques that became the basis for self-cultivation practices. These self-cultivation practices form the core of early Daoist philosophy. Daoist cosmology (a branch of metaphysics that deals with the nature of the universe) and political philosophy developed around these self-cultivation techniques.

Inward Training

For centuries scholars were aware that the composite work known as the Guanzi contained Daoist essays. Roth provides a translation and analysis of the “Inward Training” chapter of the Guanzi, arguing that it is an example of an early Daoist meditation manual. The “Inward Training” chapter discusses the vital essence (jing), the vital energy (qi), and the means by which humans can gain control over these life-giving forces through meditation. For example, the chapter begins:

The vital essence of all things: it is this that brings them to life. It generates the five grains below and becomes the constellated stars above. When flowing amid the heavens and the earth we call it ghostly and numinous. When stored within the chests of human beings, we call them sages.

Therefore the vital energy is: Bright!—as if ascending the heavens; Dark!—as if entering an abyss; Vast!—as if dwelling in an ocean; Lofty!—as if dwelling on a mountain peak. Therefore this vital energy cannot be halted by force, yet can be secured by inner power. Cannot be summoned by speech, yet can be welcomed by the awareness. Reverently hold onto it and do not lose it: This is called “developing inner power.”
All the forms of the mind are naturally infused and filled with it [the vital essence], are naturally generated and developed [because of] it. It is lost inevitably because of sorrow, happiness, joy, anger, desire, and profit-seeking. If you are able to cast off sorrow, happiness, joy, anger, desire, and profit-seeking, your mind will just revert to equanimity. The true condition of the mind is that it finds calmness beneficial and, by it, attains repose. Do not disturb it, do not disrupt it and harmony will naturally develop. (Roth 1999, 46–50)

Daoists seek a natural life lived in harmony with nature free from anxiety and distress. Contentment or equanimity can be achieved if a person is able to get beyond selfishness, greed, and the emotional exchange between being sad versus being happy and being joyful versus being angry. Inward training instructs the reader in breath control, focusing the mind in concentration to lead the practitioner to a mystical experience of union with the dao (the way of nature), also referred to as the one. Sitting in the correct posture, making the mind tranquil, and controlling the breath to contain the vital essence are the means to hold fast to the one. Holding fast to the one is the key for controlling the myriad things and not being controlled by them. When this kind of thinking is applied to the political arena, the Daoist sage ruler uses his grasp of the dao to bring peace and harmony to the masses without micromanaging the affairs of state by emulating the forces of nature. As chapter 78 of the Laozi advises:

There is nothing in the world softer and weaker than water, but for attacking the solid and strong, there is nothing better. Nothing can substitute for it. That the weak can overcome the strong and the soft can overcome the solid, everyone in the world knows this, but none can put it into practice. Therefore the sage has said, “To receive the dirt of a country is to be the lord of its altars of soil and grain. To bear the suffering of a country is to be the king of the world.” Truth sounds contradictory. (Ivanhoe 2002, 81)

Chapter 80 of the Laozi describes a simple agrarian community as the ideal:

Ah! For a small country with few people! Though there are many contrivances, the people have no use for them. The people weigh death heavily, and won’t consider distant travel. Boats and chariots, weapons and armor they have, but there is no reason to display them. Let the people return to tying knots for keeping records. Make sure they consider their food sweet, their clothes beautiful, their homes peaceful, and their customs delightful. Although the neighboring countries are so close you
can hear their chickens and dogs, nevertheless, the people grow old and die without traveling between them.

These passages serve to show how the ruler’s self-cultivation allows him to bring peace and order to his state.

Zhuang Zhou (c. 370–301 BCE) is believed to be the author of the first seven or inner chapters of the text that bears his name, the Zhuangzi. According to his biography in the historian Sima Qian’s Records of the Grand Historian (c. 99–98 BCE), Zhuang served as a minor official in Meng in the state of Song, overseeing the lacquer garden. He declined the invitation of King Wei of Chu (reigned 339–329 BCE) to serve as prime minister. The text consists of short narrative stories, anecdotes, descriptions, aphorisms, and dialogues.

One of those stories provides some insight into Zhuangzi and his philosophy, relating how one day he is hunting in the forest when a large and odd bird swoops by, almost hitting him. Intrigued by the bird he follows it. When the bird alights on a branch, he takes aim to shoot it. Then he notices that the bird is about to catch a preying mantis, which is about to eat a cicada. Seeing himself in the interconnected web of life and death, he runs from the forest. His disciple observes that Zhuangzi is depressed for a few days and asks him why. Zhuangzi notes that he had not been seeing things clearly and had forgotten about what could happen to him. This story may relate the basis of Zhuangzi’s conversion to Daoism. Through it we gain insight into how people look at the world in their habitual and complacent manner, wrongly believing that they are in control and disconnected from the interrelatedness with other creatures in the web of life and death.

One theme of the Zhuangzi is that life is in a constant state of flux. Transformation and the ultimate transformation of death are inevitable. According to Zhuangzi, people misuse their bodies and especially their hearts. They distress their bodies in physical labor, and they put unnecessary emotional stress on the heart both as a physical organ and as the symbolic seat of thought and feeling by worrying and fretting about social expectations and conventions. The Zhuangzi contains descriptions of Daoist masters who are able to enter into deep levels of meditation, who can practice various types of deep breathing exercises and forms of concentration or “fasting the heart” (chapter 4), by which they can merge with the cosmic way.

Zhuangzi’s teachings are designed to stimulate people to see things differently, to reframe their perspectives or make a paradigm shift so they see things the way they really are. When people have a proper understanding of the world and their place in it, then they can free themselves from the burdens of social conventions and bad habits that cause them stress and shorten life. Zhuangzi’s philosophy is designed to make people challenge their basic assumptions about themselves, others, and the world. Coupled with breathing exercises and meditation, the renewed outlook on life allows people to cut loose (jie) from binding restrictions, opening them to clarity or enlightenment.

Toward the end of the Warring States period (475–221 BCE) Daoism began to take on more of a political focus, resulting in the development of a political Daoism.

Huang-Lao Daoism

Some legalist-minded philosophers such as Shen Dao (flourished 350–275 BCE) and later Han Fei (d. 233 BCE) saw an affinity between Daoist cosmological ideas and the art of rulership. A political movement began that drew from both legalism (strict, literal, or excessive conformity to the law or to a religious or moral code) and Daoism; a political form of Daoism arose that was based on the teachings of the legendary Yellow Emperor (Huangdi) and Laozi that became known as “Huang-Lao.” One copy of the Laozi that was excavated from the tomb of a minor official at Mawangdui in 1973 has four essays attached to it. Because those four essays contain dialogues with the Yellow Emperor, some scholars consider them to be the lost Four Classics of the Yellow Emperor. In keeping with the eclectic character of political philosophy at the end of the Warring States period, these four essays present composite and amalgamated theories of rulership. They exhibit a family resemblance to the Laozi. For example, the Laozi emphasizes being like water, being flexible and practicing female characteristics, and staying behind to take the lead. The Four Classics display similar concerns. The “Sixteen Classics” section of the Four Classics proposes that those who take the lead have bad luck and that
those who stay behind have good luck. The text proposes that if people adhere to the feminine model, they can act first and have good luck. If they adhere to the masculine model and stay behind, they will have bad luck.

Other texts from the end of the Warring States period and the early Han dynasty (206 BCE–220 CE) employ the eclectic, amalgamated political philosophy that has been labeled “Huang-Lao,” such as the Lushi chunqiu (c. 241 BCE) and the Huainanzi (c. 122 BCE). Daoist and yin/yang ideas were also borrowed by the early Han Confucian scholar Dong Zhongshu (flourished 179–104 BCE). Under Emperor Wu of the Han dynasty (reigned 141–87 BCE), Dong Zhongshu help make an eclectic and practical form of Confucianism the state ideology. During Emperor Wu’s reign the Laozi was chanted in court ritual. After philosophical Daoism had been absorbed into Han Confucianism, toward the end of the Han dynasty a minor official, Zhang Ling, claimed to have received revelations from the deified Lord Lao in 142 CE. Zhang’s teachings are called the “Sworn Oath of the Orthodox One,” and he began a liturgical tradition of the Celestial Masters that continues to this day. This tradition expanded on the sparse moral teaching found in the Laozi, making morality an important factor in a person’s ability to merge with the dao, attaining physical immortality.

**Seven Worthies of the Bamboo Grove**

After the Han dynasty collapsed the geographical area of China was fragmented and ruled by fourteen minor dynasties, beginning with the Wei dynasty (220–265 CE) and ending with the Northern Zhou (557–581 CE). During this period of political fragmentation philosophical Daoism experienced a revival. As the aristocratic families and the scholar-officials came into or fell out of favor with the ruling family, people’s livelihoods and even their lives were constantly in jeopardy. Especially when scholars fell out of favor with the court, they often turned to Daoist teachings and self-cultivation practices to both occupy their time and to find a way to cope with political changes or disasters and to avoid being executed. Like the Warring States period, the Three Kingdoms period (220–265 CE) and the North and South Dynasties (220–589 CE) were a time of cultural creativity and philosophical development. Buddhism was taking root in China. The uniquely Chinese sect of Buddhism known as “Chan”—or in Japanese “Zen”—Buddhism developed under the influence of the Zhuangzi. In large part the iconoclastic and shock-effect teaching style of the Zen masters is drawn from Zhuangzi’s philosophy. Whereas the Zen monks sought enlightenment in the monastery, and the Daoist priests performed elaborate esoteric rituals, the Daoist philosophers entertained themselves with pure conversations (qingtian) and profound metaphysical studies (xuanxue) while engaging in heavy drinking in their favorite bamboo groves. Inspired by Zhuangzi’s mystical union with nature, seven philosophers known as the “seven worthies of the bamboo grove” rejected the trappings of society and removed themselves from the fetters of politics. One worthy, Liu Ling (d. 265 CE), was noted for his love of wine. His poem, entitled “In Praise of the Power of Wine,” draws images and expressions from the Zhuangzi. Two other worthies, Xiang Xi (d. 300 CE) and Guo Xiang (d. 312 CE), wrote commentaries on the Zhuangzi. Guo Xiang further developed Zhuangzi’s philosophy. He especially expanded the concepts of spontaneous nature (ziran) and unperceivable existence (wu) and getting beyond the purposive mind (wuxin) and acting without purposive action (wei wuwei). Wang Bi (226–249 CE) was a Confucian scholar by training, but his commentary on the Laozi has left a lasting impression on the way people read that text. Wang Bi helped readers understand the significance of spontaneous nature and the concepts of emptiness (wu) and unperceivable existence (wu). He Yan (d. 249 CE) was also a Confucian by training and, like Wang Bi, celebrated Confucius, not Laozi, as the sage. He Yan helped develop the notion that the dao is beyond language and nameless. Ruan Ji (210–263 CE) promoted the Daoist concept of nature mysticism, becoming one with nature. He argued that people are held back by social conventions, especially passing value judgments on others and themselves. The last member of the seven worthies was Xi Kang (223–262 CE). Like Ruan Ji he advocated cutting loose from the fetters of social convention, especially the distinctions of right and wrong, wealth and poverty, and noble and humble status in society.

During the Tang dynasty (618–907 CE) Daoism received imperial patronage. The Laozi and the Zhuangzi, along with the Confucian classics, were accepted as
official texts for the civil service examination. Religious Daoism and Daoist alchemical practices were popular. A Tang text and diagram called the "Diagram of the Great Ultimate" (Taiji tu) was developed as an alchemical document. This text was transmitted through a series of Daoist masters until it was given to Zhou Dunyi (1012–1073). Zhou Dunyi was considered to be the father of Song dynasty (960–1279) neo-Confucianism by the neo-Confucian synthesizer Zhu Xi (1130–1200). Both Zhou and Zhu wrote commentaries on the "Diagram of the Great Ultimate." In this way important Daoist philosophical ideas influenced the subsequent development of neo-Confucianism. Daoism continued to offer inspiration and solace to disenfranchised scholar-officials during the final dynasties. Today Daoism continues to inspire philosophers around the globe. Aside from popular books on topics such as the dao of cooking or the dao of pleasure, scholars continue to seek inspiration from Daoism to develop theories of linguistic meaning, environmental ethics, political theory, cosmology, and astrophysics. Daoism is a philosophy of change, and it has continued to change itself and survive.

James D. SELLMANN

Further Reading

Daoism is an important Chinese philosophical and religious tradition. Its doctrines, institutions and practices have had a profound impact on cultural, social, and religious life in China through the ages.

Daoism (Taoism) is an indigenous Chinese religion that has had a great impact on Chinese philosophy, art, literature, science, medicine, and martial arts. The word dao 道 (often tao) literally means “the road, the path,” yet it is translated as “the Way” in Western-language scholarship. Along with Confucianism and Buddhism, Daoism is often viewed as one of three institutionalized or organized religious traditions in imperial Chinese society. Contemporary scholars still debate the similarities and differences between Daoism and popular religion.

Daoism as a religion (Daojiao 道教) has its root in Daoism as a philosophical tradition (Daojia 道家). Two classics, The Book of the Way and Its Virtue (Daodejing 道德經) and Zhuangzi (莊子), serve the textual foundations for Daoist philosophy and religion. The Daoist philosophical tradition originated from The Book of the Way and Its Virtue (Daodejing), commonly dated to around 400 BCE. This book is also entitled Laozi, which indicates that it is attributed to the fourth-century BCE philosopher Laozi (Old Master). (Some scholars argue that Laozi lived as early as the sixth century BCE, while others consider him to be a fictional figure despite a record of his life written by Han dynasty [206 BCE – 220 CE] court biographer Sima Qian [c. 145 – 86 BCE].) Nevertheless this book was compiled and revised with clarity and coherence during a long period and probably by many authors. Historically, the rise of Daoism as a religion occurred in the later Han dynasty, around the second century CE, when Laozi was deified as “Most High Old Lord” (Taishang laojun).

The Book of the Way and Its Virtue contains roughly five thousand Chinese characters and is organized into eighty-one chapters. In this work the Daoist cosmology (a branch of metaphysics that deals with the nature of the universe) is centered on the concept of chaos (hundun). According to The Book of the Way and Its Virtue, dao is not definable. It exists in all things (wanwu, ten thousand things). The Way is present in the process of the change and transformation of all things in nature and in society. The Way cannot be named, and it is also beyond human perception because it is said that, “The Tao (Way) that can be told is not the Eternal Tao; the Name that can be named is not the Eternal Name.” (Chan 1963, 139). If one comprehends the Way and acts naturally, it is wuwei, literally nonaction, nonwillful action in Daoism. Wuwei is viewed as the right way of life. The Book of the Way and Its Virtue also teaches correlatives as the expression of the movement of the Way, representing some pairs of forces such as yin and yang, male and female, active and passive, as well as excess and defect. It manifests the ideal portrait of the holy person (shengren), who empties himself, living naturally and staying with plainness. A holy person is the one who achieves harmony. Zhuangzi, on the other hand, is a book that was written by Zhuang Zhou, also known as Zhuangzi, Master Zhuang (c. 370 – 301 BCE). It reveals some other important concepts in Daoism, such

© 2009 by Berkshire Publishing Group LLC
as that of immortals. In Zhuangzi people are said to exist in the process of constant change and transformation. It also teaches some techniques, including meditating and breathing to facilitate this transformation.

Besides the intellectual resources of Daoist philosophy, in its long history the Daoist religion borrowed many elements from Chinese popular religion such as yin and yang, the Five Elements (wuxing), shamanism, and methods of esoterica (fangshu). Although Daoist philosophy appeared around the fifth century BCE, the rise of Daoist religion occurred in the later Han dynasty.

Divine Figure

In Daoist religion the Way becomes a mystical concept. Echoing The Book of the Way and Its Virtue, The Scripture of Great Peace (Taiping jing) states that the Way is the origin of all things and cannot be named, and that the Way is the root and master of the great transformation. It also claims that the Way is too profound to be perceived. By the second century CE Laozi was considered a divine figure who was believed to be the incarnation of the Way. The Way was the One, and the One could diffuse to be ether. The ether gathered to become the Most High Old Lord. This figure was the parent of the heaven and earth, the authority of the yin and yang and the ruler of all deities. In the North and South Dynasties (220–589 CE, also known as the Six Dynasties), The Way became the Celestial Venerable of the Primordial Beginning (Yuanshi tianzun), the highest god in Daoism. With Daoism’s rise as a religion during the Han dynasty it inherited some popular techniques for pursuing longevity. The techniques for achieving longevity and nourishing life also helped practitioners escape danger when under attack by beasts and engaged in war. These techniques attracted many followers who suffered during the period when the Han dynasty nearly collapsed.

Immortals are celestial beings in Daoism. They are also called “transcendent beings” because they are physically and spiritually immortal and beyond this world. They enjoy the longevity of life and immortality. In some texts they also appear as divine immortals (shenxian), divine persons (shenren), and immortal sages (xiansheng). The idea of immortals can be found in two early Daoist texts, Zhuangzi and Liezi. However, the most famous work about immortals is a collection entitled Biographies of Divine Immortals or Traditions of Divine Transcendents, (Shenxianzhuan). This work contains more than one hundred hagiographical (relating to the biography of saints or venerated persons) stories about divine immortals. It was attributed to Ge Hong (283–343 CE); yet, most of the stories were likely to have been written after the sixth century CE. These stories teach that immortality can be achieved by bodily and spiritual cultivation. Ge Hong suggests that three forms of immortality exist: celestial, earthly, and corpse liberated. In order to achieve immortality, one should practice ether (qi) techniques. Other practices, such as meditation, visualization, and rituals, are also vital in the pursuit of immortality.

Daoist Canon

The Daoist canon, like the Buddhist canon in the Mahayana tradition, is an expandable corpus of Daoist scriptural, scholastic, and historical texts. The canon also frequently appears as the Complete Scriptures of Daoism (Daojiao yiqie jing) because it includes both scriptures and other genres. The current Daoist canon commonly used in the scholarly world is called the Daoist Canon of the Zhengtong Reign Period (Zhengtong daozang), which was compiled in 1444–45. This canon has 5,485 fascicles (the divisions of a book published in parts). In the North and South Dynasties, Daoist masters Ge Hong and Lu Xiujing (406–477 CE) laid the foundation for cataloguing early Daoist texts. Later the Tang dynasty (618–907 CE) emperor, Xuanzong, ordered compilation of the first complete set of the Daoist canon. This version was enriched during the Song dynasty (960–1279), Jurchen Jin dynasty (1125–1234), and Yuan dynasty (1279–1368). Nevertheless, the Daoist Canon of the Zhengtong Reign Period is the latest version. In the twentieth century numerous Daoist manuscripts from the city of Dunhuang in Gansu Province were compiled by scholars from all over the world.

The Daoist Canon of the Zhengtong Reign Period comprises seven sections: the Three Caverns (sandong) and the Four Supplements (sifu). The Three Caverns are three divisions of Daoist texts: the True Cavern (Dongzhen, the Superior Cavern), the Mystical Cavern (Dongxuan, the Middle Cavern), and the Spiritual Cavern (Dongshen,
the Lesser Cavern). Each division has a group of original Daoist texts. The Scriptures of Upper Purity (Shangqing jing) constitutes the core of the True Cavern. The Scriptures of Numinous Treasure (Lingbao jing) constitutes the core of the Mystical Cavern. And the third division was developed based on the Scripture of Three Sovereigns (Sanhuang jing).

In Daoism the Three Caverns are linked with Three Purities and Three Vehicles. The True Cavern and the Jade Purity are the Great Vehicle, the Mystical Cavern and the Upper Purity are the Middle Vehicle, and the Spiritual Cavern and the Great Purity are the Small Vehicle. The Four Supplements are four portions of the Daoist canon with the titles of the Great Mystic (Taixuan), the Great Peace (Taiping), the Great Purity (Taiqing) and the Orthodox Unity (Zhengyi). The Great Mystic is based on Laozi. The Scripture of Great Peace is the central text in the section of the Great Peace. The Great Purity contains a group of texts on alchemy. The canonical texts of the Way of Celestial Masters constitute the core of the section of Orthodox Unity.

Earliest Traditions

Unlike with many of the world religions, such as Buddhism, Christianity, and Islam, with Daoism it is difficult to tell when it became a religious tradition and precisely who founded it. Generally speaking, the earliest traditions of Daoism were the Way of the Yellow Emperor and the Old Master (Huanglaodao) and the Way of Five-Pecked Rice (Wudoumidao) in the Han dynasty. In the tombs of Mawangdui 馬王堆, a site near present Changsha, Hunan Province, some silk scrolls of Daodejing were uncovered, revealing the ideas of Qixia Academy of the Ji kingdom associated with the Way of the Yellow Emperor and the Old Master. This tradition promotes the ideas of renunciation of wealth and the pursuit of longevity.

In the later Han dynasty the Way of Celestial Masters (Tianshidao) was developed from two movements: the Yellow Turbans (Huangjiao) movement in central and eastern China and the Way of Five-Pecked Rice movement in the Hanzhong area (modern southern Shaanxi Province). The first movement was also called the "Way of Great Peace" (Taipingdao), and under the leadership of Zhang Jue this movement rose up against the Han central government in 184 CE. Its followers venerated the Yellow God and believed that a new era under the reign of Yellow Heaven was coming. They sought a kingdom with harmony, peace, wisdom, and equality—a utopian reign. The Daoist text Scripture of Great Peace (Taiping jing) played a crucial role in inspiring this movement. The Scripture of Great Peace mixes Daoist cosmology and yin and yang as well as Five Elements (wuxing) theories. It teaches that divine messengers, celestial masters (jianshi), would bring revelations to this world for the sake of people who suffered under the Han regime. By movement toward a state of nonaction, the great peace would be achieved. The Way of Five-Pecked Rice was established by Zhang Ling (Zhang Daolin, the Celestial Master Zhang), who was a leader of a group of small landowners in the southern Shaanxi area. This group aimed to establish a religious ideology through which the mandate of the Han court would be removed by the god Most High Old Lord. And the celestial masters would rule the people by the will of this Most High Old Lord. The members were required to contribute five-pecked rice to the group, which was the practice of the origin of the name of the group. After Zhang Ling died, his son Zhang Lu continued to lead the group as a local autonomous power. Yet, in 215 CE he...
handed over his power to the central government but retained his tradition.

During the period of the North and South Dynasties, especially during the Eastern Jin dynasty (317–420 CE), Daoism flourished, especially in southeastern China. The aristocratic class was involved in writing and practicing Daoism, thereby contributing to the formation of the early Daoist canon and Daoist rituals. Two traditions, Upper Purity (Shangqing) and Numinous Treasure (Lingbao), appeared to be significant during this period. The Upper Purity tradition is named after the Scriptures of Upper Purity. This tradition focuses on the cultivation of essence (jing), ether (qi), and spirit (shen) by which one can cultivate his or her body. This practice was particularly favored by elite literati. The Numinous Treasure tradition is named after the Scriptures of Numinous Treasure. It is said that this section of Daoist scriptures was initiated by Ge Xuan (164–244). Ge Xuan then transmitted it to his disciple Zheng Yin (215–302). Zheng Yin taught it to Ge Hong (284–364), who promoted this tradition to a new stage. Liu Xiujing during the Liu Song period (420–479 CE) enriched it with many rituals and precepts. This tradition focused on rituals and precepts rather than alchemy and sexual technique. It may be closer to the former Way of Celestial Masters than to the Upper Purity tradition. Later Tao Hongjing (456–536) became another important contributor to the development of Daoism in Southern dynasties (420–589 CE). Tao Hongjing helped create a mature Daoist pantheon based on worldly hierarchical structure. He also compiled a work entitled the Perfected Declaration (Zhengao), which preserved abundant sources about the early history of Daoism. He also developed some new techniques for Daoist cultivation.

During the Northern dynasties (386–581 CE) some remarkable developments occurred into Daoism. For instance, Daoist religion as a tradition was guarded and protected by the Kou clan. The most distinguished Daoist in this clan was Kou Qianzhi (365–448), who claimed that he received revelations from the Most High Old Lord and his offspring in the Mountain Song in 415 and 423. He reformed the old Daoist tradition inherited from the Zhang family in the later Han dynasty. His innovations enhanced aspects of the creating rites, the observing precepts, and the creating cinnabar (artificial red mercuric sulfide used especially as a pigment). He also composed scriptures. Later he served the court of the Northern Wei (386–534 CE) emperor, Taiwudi. Because of Kou Qianzhi’s influence, in 446 the emperor issued an edict ordering the suppression of Buddhism. During the later Northern dynasty, Daoism, along with Buddhism, as an important religious tradition was given a section in an official history, the History of Wei (Weishu) by Wei Shou (506–572).

After the Sui dynasty (581–618 CE) Daoism was challenged, first by the flourishing of Buddhism during the Tang dynasty (618–907 CE) and then by the revival of Confucianism during the Song dynasty (960–1279). During the late Northern Song dynasty (960–1126) Daoism became a subject in the civil examination. From the Southern Song dynasty (1127–1279) to the Jurchen Jin and Yuan dynasties Daoism experienced what contemporary scholars called the “revival of new Daoism.” During this revival three new movements—Great Unity (Taiyi), True Great (Zhenda), and Complete Perfection (Quanzhen) appeared.

During the Yuan dynasty emperors particularly favored the Complete Perfection movement. One of its leaders, Qiu Chuji (1148–1227), even accompanied Mongol conqueror Chinggis Khan (often spelled Genghis Khan) in his travels to the western regions in central Asia. During the Ming (1368–1644) and Qing (1644–1912) dynasties the new trend in religious development was the unification of the three religions, Confucianism, Buddhism and Daoism. During the late Qing dynasty and the early Republican period (1912–1927) all three religions experienced a crisis with the political decline of the Chinese empire. The revival of Daoism appeared only after the 1980s, yet it remained far behind Buddhism.

**Daoism, Confucianism, and Buddhism**

People often view Daoism, Confucianism, and Buddhism as the three organized religions in China. However, historically Confucianism was always seen as heading the three religions during most regimes through the ages. Daoism absorbed many Confucian ethical ideas during its early development, ideas such as seeking self-cultivation in morality and serving family and country, as Ge Hong

Daoist Rituals, Festivals, and Mountains

The term inner alchemy is a translation of the Daoist term neidan, referring to a series of ways in which one can achieve the transcendent state or a return to the original order of the cosmos. The practice of inner alchemy creates inner elixir and controls the motion of the mind, the breath, and the body in order to pursue longevity. In Daoist philosophy inner alchemy combines naturality (xing) and fate (ming). Xing, in Daoist terms, means the original inactive state of a being. Yet, ming refers to fate, the destiny of a being, which is the perfect nonaction. In the practice of inner alchemy three ingredients occupy the central positions: essence (jing), ether (qi), and spirit (shen). Essence might be brought up by one’s birth or might be derived from the digestion of food. Essence, ether, and spirit might appear as the forms of human bodily fluids. Two types of ether exist: primal ether and true ether. Primal ether arose from the creation of the universe; true ether arose from breath, from drinks and food. Two types of spirits exist: the original spirit and the spirit of knowing. The former is the unconscious functions of the nervous system, and the latter is the consciousness and thought in the learning process.

Spells and talismans are also commonly used in Daoist practice. They might have been derived from the influence of Buddhism and traditional Chinese religion, but later Daoism certainly revised them. Clearly spells might have been borrowed from esoteric Buddhism; however, talismans were borrowed from shamanism. The adaptation of Daoist talismans was also inspired by the Book of Changes (Zhouyi). It used modified Chinese characters and consecrated them with divine powers based on Daoist precepts. In Daoist practice talismans authorized the actions of the deities and the demons, healed illness, and bestowed the good sign to believers. Yin Yang and Five Elements also played important roles in the application of talismans and spells. The four cardinal directions in Daoism are represented by four symbolic animals and figures: Blue Dragon of the East (Qinglong), Red Phoenix of the South (Zhuque), White Tiger of the West (Baihu), and Dark Warrior of the North (Xuanwu).

Daoism observes many celebrations and festivals. The ninth day of the first month in the lunar calendar is the birthday of the Jade Emperor, with prescribed rituals and offerings. Three important festivals in Daoism are the Three Primes (Sanyuan). The Upper Prime Festival (Shangyuan Festival, now Yuanxiao Festival or Lantern Festival) is held on the fifteenth day of the first month in the lunar calendar. On the night of this festival lanterns are displayed, and people come out to watch the lantern show. The Middle Prime Festival (Zhongyuan Festival) is held on the fifteenth day of the seventh month in the lunar calendar. On this day people feed the spirits of deceased ones. The Lower Prime Festival (Xiayuan Festival) is held on the fifteenth day of the tenth month.

As do other religions, Daoism views some mountains as sacred. The most famous four sacred mountains for Daoists are Mount Wudang in Hubei Province, Mount Longhu in Jiangxi Province, Mount Qiyun in Anhui Province, and Mount Qingcheng in Sichuan Province. Mount Wudang is famous in recent years for its long tradition in Chinese martial arts. It has appeared in action movies, for instance, in the Oscar-winning film Crouching Tiger, Hidden Dragon. Mount Longhu
(Mount Dragon and Tiger) is the seat of the Way of Celestial Masters.

Daoist Temples have been found throughout China since 25 CE. They provide a place for spiritual improvement and training, as well as a place to take part in Daoist religious activities. Only a handful of Daoist temples remain as cultural heritage sites for Daoists and tourists alike.

Daoism was founded during the early Han dynasty (206 BCE—220 CE). At this time believers needed a simple place to gather for meetings or to conduct religious practices. Because there were no set requirements for a Daoist temple, the architecture tended to be plain: simple buildings with simple furniture inside. Taipindao, one sect of Daoism, called these kinds of places “thatched cottages,” whereas Wudoumidao, another sect, called them “quiet houses.”

During the Three Kingdoms period (220–265 CE) and the North and South dynasties (220–589 CE), as Daoism gradually became more active with more adherents, Daoist worshippers began to call Daoist structures jing or “peaceful houses.” Daoism eventually grew to become the official religion of the imperial family, who worshiped Laozi, one of the main figures in Daoism, as an ancestor. Between 386 and 581 CE, Daoist structures could be found in nearly all parts of China. The general configuration of Daoist temples was established during the Tang and Song dynasties. When the Tang dynasty (618–907 CE) came to power, Daoist architecture included structures

A Daoist Temple. In the third century Daoist worshippers began to call their temples jing or “peaceful houses.” PHOTO BY JOAN LEBOLD COHEN.
such as “peaceful houses” in which ordinary people could worship; temples, for priests and officials; and palaces, for members of the imperial family. These structures could be found close to the imperial palace. By the end of the Tang dynasty in 907 CE, China had sixteen hundred Daoist temples and palaces. The emperor of the Song dynasty (960–1279) continued to praise Daoism. Emperor Huizong even ordered the building of a Daoist temple in every province and prefecture.

Daoist temples are built according to the law of symmetric arrangement along a center axis, but they also are designed according to the terrain if the temple is on a mountain. Daoist temples differ in scale and composition. They also differ in usage: Some are palaces for gods’ statutes, some are houses for priests to practice Daoism, some are places for ritual, and some are libraries.

Daoist temples remaining in China today belong to different sects of Daoism. Those belonging to the Quanzhen sect are the most popular in northern China; Louguan Temple in southeast Zhouzhi County, Shaanxi Province, is the oldest Daoist temple in China. It is said that Yinxi, an official of Hanguguan Pass during the Zhou dynasty (1045–256 BCE), even welcomed Laozi to this temple, where Laozi related the Daodejing to Yinxi before leaving the central plains for the west. Because the Quanzhen sect gained power during the Jurchen Jin dynasty (1125–1234) and Yuan dynasty (1279–1368) in this area, Louguan Temple was incorporated into the Quanzhen sect.

Another famous temple of the Quanzhen sect is the White Cloud Temple in Beijing. It was founded in 739, enlarged in 1174, and became the largest Daoist temple in northern China. Because Mongol conqueror Chinggis
Khan (also called Genghis Khan, 1162–1227) of the Yuan dynasty invited Qiu Chuji, a famous Daoist priest of the Quanzhen sect, to live in this temple, and because the director of this temple, Wang Changyue, was given the title of bishop during the early Qing dynasty (1644–1912), the Quanzhen sect regarded this temple as its central temple.

Yonglegong Temple, located in Yongji County, Shanxi Province, also belongs to the Quanzhen sect. It was founded during the Tang dynasty to memorialize Lu Dongbin, one of the famous eight Daoist immortals, and enlarged in 1262. Its main architecture—such as the Daoist Trinity Palace, Chunyang Palace, and Chongyang Palace—has many wonderful frescoes.

Another important group of Daoist temples is on Wudang Mountain in Hubei Province. These temples were built during the early Tang dynasty. However, the largest construction in the history of Daoism in China was in 1413. The project required the labor of 300,000 people for eleven years. It included eight palaces, two temples, thirty-six halls, and seventy-two shrines. Thus, the Wudang Daoist temples are rare in scale in China.

近朱者赤，近墨者黑

Jin zhú zhě chì, jìn mò zhě hēi
Daqing, a city in northeast China, was formally founded in 1959 to develop the country’s largest oil fields. For many years a model of efficiency and national industrial practice, Daqing was the site of huge protests in 2002 after the central government applied pressure to cut back the workforce in the oil fields and trim some of the social benefits offered to current and former employees.

In the mythology of contemporary China, Daqing holds a particular place, both as a city held up as a model of efficiency in the 1960s and 1970s and as the location of the heroic deeds of model worker Wang Jinxin (1923–1970), known as “Iron Man Wang.” Since 1964, Daqing has also been linked with Dazhai, a national agricultural model, in the central northern province of Shanxi. Chinese Communist Party leader Mao Zedong’s statement in 1964—“In agriculture learn from Dazhai, in industry learn from Daqing”—was endlessly repeated and set down as cast-iron truth until his death in 1976.

Daqing has continued to be important to China’s development, however, whereas Dazhai has proven to be a tragic fraud, its party secretary, the barely literate peasant Chen Yongui, felled from the positions he had been elected to as a result of Dazhai’s elevation in the late 1970s and the whole project exposed and discredited.

Daqing is a city in the northeastern province of Heilongjiang, bordering Russia. Prospecting for crude oil began in the area in 1959 but was energized by a call by Mao Zedong and the Chinese Communist Party Central Committee to greatly expand production in February 1960. This development occurred against the backdrop of arguments with the USSR and an increased need for China to be self-sufficient in energy production. In the propaganda carefully constructed afterward, “Iron Man Wang” was summoned from oil fields in the western province of Gansu with the brigade he headed, Drilling Team 1205, to open up Daqing. Wang was rewarded for his efforts by becoming a national labor model in 1967 and being elected to the Ninth Central Congress in 1968. He was a figure familiar to followers of Cultural Revolution (1966–1976) iconography and hagiography (biography of saints or venerated persons), in which he was often said...
to battle against class enemies and revisionists. Daqing, in fact, was built by more than forty thousand workers, using 700,000 metric tons of equipment, becoming fully operational in 1963.

Daqing would eventually produce almost 2 billion metric tons of crude oil and become the world’s fourth-largest oil field and the largest in China. Other potential sources, such as Xinjiang and the Bohai Sea, were to prove either too remote or too difficult to exploit economically. Although for twenty-seven years (up to 2005) Daqing produced 50 million metric tons of oil a year, predictions showed that by 2010 production would fall to 30 million metric tons and to 20 million metric tons by the end of 2020, despite efforts to locate another 500 million metric tons in the area. This decrease in production has occurred as China’s own energy needs have burgeoned, making it the world’s second-largest user of crude oil after the United States and, beginning in 1993, a net importer of oil. China’s attempts to acquire long-term supplies in the Middle East and Africa have caused considerable geopolitical problems, despite plans between Russia and China in 2002 to construct a pipeline between Siberia and Daqing. Daqing still accounts for one-third of China’s oil production.

The slogan to “learn from Daqing” was revised in the 1980s, particularly after the Tiananmen Square incident in June 1989, where Daqing was once again held up as a model of efficiency and national industrial practice. However, in the 1990s, with many of the state-owned industries around it in the northeastern “rustbelt” region, it came under pressure from the central government to trim its workforce and cut back some of the social benefits that it gave to current and former workers. By 2002 this action had resulted in mass protests in the city that attracted international attention both for their size (one commentator claimed they were the largest industrial protests in China since 1949) and for the fact that they were occurring in a place once held up as a model commune. Although the protests were quelled, officials made no further attempts to revive the “learn from Daqing” campaign. However, as perhaps a tribute to the city’s role in the development of China, in summer 2008 Daqing was one of the cities through which the Olympic torch passed on its way to Beijing for the games.

Dayan Pagoda

Dàyàn Tǎ 大雁塔

One of the oldest extant Chinese pagodas, the Dayan (Big Wild Goose) Pagoda in the temple complex of Da Ci’en monastery in Xi’an city, has been a repository of Buddhist relics and an historic example of Tang architecture and art since it was built in 652 CE.

The Dayan (Big Wild Goose) Pagoda is located in the southeastern sector of present-day Xi’an city, Shaanxi Province. Completed in 652 CE in Chang’an, the capital city of the Tang dynasty (618–907 CE), the pagoda became part of the Da Ci’en monastery (Temple of Great Maternal Grace). Da Ci’en temple had been established earlier by the Tang crown prince, who later became Emperor Gaozong (628–683 CE), in memory of his deceased mother. The temple also served as the home monastery for the monk Xuanzang (c. 602–664 CE) after his return to Chang’an in 645 CE from the Indic regions of Asia. The Dayan Pagoda was used to store the Sanskrit texts and Buddhist relics Xuanzang transported from that journey, and it was the place where he carried on the project of translating Buddhist sutras. (Xuanzhang’s travels to India were the basis for the adventures of the monk and his monkey guide in the Ming-era’s Journey to the West, to this day one of China’s most popular novels.)

This multi-tiered building (64.839 meters in height) is a result of a series of restorations and renovations over the original five-story, brick-layered earthen structure, which collapsed soon after its completion. The damaged structure was refurbished (from 701 to 704 CE) to become a seven-story building, presumably reaching its current height. It came to be known as the Big Wild Goose Pagoda, a name borrowed from a stupa in Central Asia, a huge, dome-shaped Buddhist shrine where Buddha was said to be present in the form of a flying goose (hamsa in Sanskrit).

The Dayan Pagoda was the sole surviving structure within the Da Ci’en complex when the temple was reduced to ruins during the incessant military conflicts in the Chang’an region toward the end of the Tang dynasty, but its basic features were preserved with a brick veneer over its old outer walls made during the Ming dynasty (1368–1644). The enduring pagoda subsequently suffered minor damages due to severe earthquakes (in particular those of 1556 and 2008), and recent threats from a growing number of subterranean termites also have become a concern for preservation.

The clean-lined, massive structure is built in Chinese louge style (a combination of multi-story structure and pavilion)—and can be simply described as a tower made from a tapering stack of graduated squat “blocks” sitting on top of a square platform (4.2 meters in height and 48 meters long on each side). The roofs protruding from all four sides of each story have tiled eaves and corbelled cornices characteristic of Tang masonry structures; the outer walls of the tower are embellished with brick works featuring arched doors, simulated timber designs of flat pilasters, simple brackets, and inter-columnar struts, all of which recall the usual attributes of carpentry works on timber-framed buildings most prevalent in ancient Chinese architectural tradition. Inside are steps that provide
access to the top of the pagoda and to the wooden land-nings on each of the square tiers; a central vertical void symbolizes the Heavenly Pillar, an imagined passageway to the celestial world.

The stone carvings on the Big Wild Goose Pagoda represent some rare examples of the talents of Tang artists. Inscriptions on stone tablets at the base of the building are said to have represented works of famous calligrapher Zhu Suiliang (596–658 CE), and Tang-style Buddhist imageries are carved on the lintels on the first floor. The fine linear designs on top of the western door, depicting the seated Buddha and his entourage in a wooden hall, have remained legible enough to shed important light on representational art of Tang era. These carvings are regarded as major sources of reference to Tang and pre-Tang architectural styles that can hardly be visualized today, as well as for studying the evolution of ancient Chinese architectural styles in general.

The Dayan Pagoda has remained a symbol of the history and literature of Buddhism in China for twelve centuries and is one of the oldest and most enduring members of the Chinese pagoda tradition.

Dazangjing (Great Treasury Scriptures)

Dàzàngjīng 大藏經

Dazangjing 大藏經 refers to Chinese Buddhist canon known as the Great Treasury Scriptures. The canon was expanded and modified through the ages for more than one thousand years.

The word Dazangjing 大藏經 literally means “Great Treasury Scriptures” and refers to the Chinese Buddhist canon. In Chinese the word zang 藏 renders the Sanskrit word pitaka (basket), which refers to the vessel that contained the scriptures, resting on palm leaves, in the early Buddhist tradition. The Chinese word jing 经 renders the Sanskrit word sūtra (scripture). The early Buddhist canon is called “Tripitaka” in Sanskrit, which literally means “three baskets,” and comprises three categories: the Sūtra pitaka (jing 经 scriptures), the Vinaya pitaka (lü 律 monastic code), and the Abhidharma pitaka (lun 论 treatises). These texts were originally written in Sanskrit and other central Asian languages. The earliest Tripitaka was the Pali canon, which developed out of three Buddhist councils held from the fifth to the second centuries BCE.

Although the early Tripitaka was endorsed by Buddhist councils, the Chinese canon itself was usually authorized by the imperial government. As a result, the early Tripitaka was never completely translated into Chinese. The Chinese Buddhist canon was known by a number of other terms in addition to Dazangjing. These terms include Zhongjing (Assembly of Scriptures), yiqiejing (All Scriptures), and neidian (Inner Scriptures). The earliest appearance of the term Dazangjing was in a biography of Tiantai School founder Zhiyi (538–597), written in the Sui dynasty (581–618 CE) by Zhiyi’s disciple Guanding (561–632). However, as a term referring to the Chinese Buddhist canon, Dazangjing gained popularity only in the Song dynasty (960–1279), when a special official unit, the dazangjingsi 大藏經司 (Bureau of the Great Treasury Scriptures), was established to take charge of the canon’s printing and circulation.

While the early Buddhist canon consisted exclusively of the three categories mentioned earlier, the Chinese version followed the Mahayana tradition, whose flexible canon was one of its distinguishing features. Thus, the Chinese canon expanded beyond translations from the original three “baskets” to include texts written by Chinese monks and laypeople. These texts represent numerous genres, including commentaries, histories, biographies, gazetteers, travel accounts, temple records, and inscriptions.

The late Tang dynasty (618–907 CE) witnessed dramatic innovations in wood-block printing, ushering in the golden age of Chinese Buddhist scripture. In the Kaibao period (971–983 CE) of the Song dynasty the first printed edition of the Chinese Buddhist canon was completed. This edition used 130,000 wood blocks; a complete set of the pages consists of 5,048 fascicles (small or slender “installments”). In later dynasties many updated editions emerged. In the Liao dynasty (907–1125) the canon was even carved on stones, which have been preserved in the Yunjusi Temple (Cloud Dwelling Temple) at Fangshan. During Japan’s Taisho period (1912–1926) Japanese Buddhists printed the most comprehensive edition of the Chinese Buddhist canon ever produced. This critical edition Taisho shinshu daizokyō (usually referred to as
Confucian Views on Suicide

Unlike common Western views, suicide in Confucian China was often viewed as praiseworthy rather than sinful.

On June 2, 1927, a famous professor of Qing Hua University, Wang Guowei, drowned himself in a lake of the former imperial garden in Beijing. His suicide proved extremely controversial and evoked much discussion. His colleague and famous intellectual, Liang Qichao, wrote several eulogies in his honor. In one of these eulogies Liang reminded his colleagues and students, who lived in a culture which had just entered the modern age and was under heavy western influence, not to use western perspectives to evaluate Wang’s suicide. Europeans, Liang asserted, used to regard suicide as an act of cowardice, and Christianity made it a sin. In ancient China, however, notwithstanding some petty suicides committed by common people, many eminent figures used suicide to express their countercultural aspirations. These were praiseworthy suicides, Liang concluded, and should by no means be rashly reproached by alien European values.

Dazhai

A small rural community in northern China, Dazhai was known as Mao’s model village. Acclaimed for its transformation to a prosperous area that turned barren hills into fertile terraced farmland, it was immortalized in the Chinese slogan “Learn from Dazhai in agriculture.”

Dazhai, located at the foot of Hutou Hill within the Taihang Mountains, is a village in Xiyang County, Shanxi Province. Before 1964, Dazhai was just a poor rural community of four hundred people, unknown to the outside world. But during the 1960s and 1970s, Dazhai attracted world attention because of the public recognition given by Mao Zedong (1893–1976) for its efforts to transform barren rugged hills into productive terraced farmlands. In 1964 Chairman Mao directed the whole nation to "learn from Dazhai in agriculture" (nongye xue dazhai, 农业学大寨), praising its production model as well as its great courage against hardship. The high yield produced on poor land was hailed as a miracle of agricultural development, and the spirit of “taming and fighting nature” (zhantian doudi, 战天斗地) was highly praised. "Learn from Dazhai in agriculture" soon became a national slogan, and in the following fifteen years, Dazhai served as a rural development model for practicing cooperation and self-reliance.

During 1940s and 1950s Dazhai had undergone land privatization and collectivization. It was liberated in 1945 from Japanese occupiers. In 1946 the village established mutual-aid teams 互助组 and later organized producers’ cooperatives 合作社 in 1953 to enhance agricultural productivity and equitable distribution of resources. In mutual-aid teams, members assisted each other during planting and harvesting, and in slack seasons, they worked on their own plots. The cooperatives system was considered an advanced form of collectivization; members gave up their land and livestock as ownership changed from private household to collective, and they worked together in the fields and shared the produce equitably. Collective farming was considered better than the single-household farming system as it was able to unify village resources and wisdom for combating the adverse conditions facing farming and living.

All the farmland in Dazhai was scattered over the ditches, patches, and slopes of Hutou Hill, and the harsh natural conditions were aggravated by natural disasters such as floods and droughts. Soil erosion had beset them for years. From 1953 to 1962 the farmers in Dazhai used rocks and soil to build stretches and then terraces. By using this method they were able to turn 120 acres of barren hillside into fertile grain fields. Even with the absence of irrigation and mechanical plowing, the grain yield increased over that ten-year period from approximately 400 kilograms to 2400 kilograms per acre. People were fed, and at the same time, they sold the surplus to the state.

In 1963 Dazhai was hit hard by a nonstop seven-day torrential rain, and the storm destroyed crops and residential homes. The residents also lost some grain in storage; the governments and neighboring villages offered help, but the people of Dazhai refused to take aid as they...
believed they could rise up again through collective power and self-reliance.

From 1964 to 1978, a time period that closely paralleled the Cultural Revolution (1966–1976), Dazhai was a highlight in media outlets and political propaganda, and it attracted millions of visitors from home and abroad, including China’s premier Zhou Enlai and many other state leaders. Dazhai drew about 5,000 to 10,000 visitors daily, which affected the villagers’ normal lives significantly. They had to organize Red Guards to maintain the order of production, which fortunately was not interrupted too much. The people knew their livelihood relied on the land and farming, and they could not afford to take it lightly.

The standard of living in Dazhai continued to improve even during the chaotic Cultural Revolution. Dazhai built better housing for each family and provided education and medical care for all using revenues generated from farming and other sources.

When China initiated reform and an open-door policy in 1978, rural areas were in the forefront of its implementation. With land reform, farm ownership changed from collective to individual households, or the so-called single household responsibility system. In the 1980s, many villages in China were undertaking huge changes due to economic reform policy, but Dazhai seemed lost and left out of the mainstream economic development. Dazhai’s “glorious history” seemed just a memory.

After a decade of silence and no major development, Dazhai was back in the spotlight with the return of Guo Fenglian 郭凤莲 in 1991. Guo had been a member of Dazhai’s famous “iron girls” work team, leading the village during the 1960s, building terraced fields and harvesting crops, defying hardships, and overcoming poor farming conditions; she became the village head in 1965 at the age of eighteen but left Dazhai in 1980 for an administrative position in the Xiyang County commission. After Guo returned in 1991 and again became the village head, she worked to improve infrastructure, the water system, and the efficient use of collectively owned machinery in the village. Under Guo’s leadership, Dazhai established a number of enterprises to absorb the agricultural labor force freed up by mechanization, including coal mining and the manufacture of construction materials, clothing, and chemicals. The village’s revenue in 2005 totaled 116 million yuan, and the yearly per-capita income reached 5,500 yuan, higher than the average rural income of the country.

If Guo Fenglian is considered a contributing factor to Dazhai’s current prosperity, then Chen Yonggui 陈永贵 should be regarded for its past glory. Chen was the Dazhai village head during 1950s and the commissary with Xiyang County in the 1960s. He led the people in Dazhai to “remake” nature; Chen was the national model farmer (laodong mofan 劳动模范) several times and made huge advances in his political career because of his work in Dazhai. In 1973, Chen became a member of national political bureau committee of the Central Communist Party, and in 1975, he was promoted to vice-premier in charge of agricultural and rural development. But he had little formal education, and the job was just too difficult; he resigned from the post in 1980. But in all his years, Chen appeared never to forget he was a farmer; he returned often to Dazhai to work together with the people in the fields, even after he became vice-premier. Chen died in 1986 at the age of seventy-three. His life and what he accomplished for Dazhai are still remembered by people today.

The forty-one sites in Dazu County in Sichuan Province contain over fifty thousand religious and secular sculptures that were carved into cliffs and caves over a 250-year period from the ninth to the thirteenth centuries.

A United Nations Educational, Scientific, and Cultural Organization (UNESCO) World Heritage Site since 1999, the rock carvings of Dazu consist of sculpted imageries and inscriptions on cliff faces widely dispersed at hillsides in Dazu County in the Chongqing area of Sichuan Province. The majority of more than fifty thousand sculptures were created by Buddhist clergy and devotees over the course of the Tang dynasty (618–907 CE), the Five Dynasties era (907–960 CE), and the Song dynasty (960–1279). They mainly pertain to Buddhist themes, although some additionally synthesize Daoist metaphysics and Confucian moralities. These carvings are noted for unique artistic temperament and rich diversity of subject matter integral to understanding the eclectic nature of visual art and the belief system of ancient Sichuan.

Of all the masterpieces of Dazu, the decorated grottos and niches at Beishan (North Hill) and Baodingshan (Treasure-Summit Hill) complexes are the most important. Artistically and iconographically, the combined works at these two locales delineate the successive phases of a blossoming religious art.

The greatest concentration of the earlier group (Tang and Five Dynasties) is located at the Fowan (Buddha Bend) site of Beishan complex, seen at cave numbers 1–98 and numbers 213–285. They constitute part of the total of 290 sets of carvings on rocky outcroppings stretching across nearly 300 meters, representing a pantheon of awe-inspiring deities and vivacious flying apsaras (celestials) familiar in pre-Tang and Tang Buddhist art. Among the visual interpretations of Tantric and Pure Land spirituality at Beishan, caves numbers 5, 9, and 10 are believed to have been pioneering works engineered around 892, at the time when a fortress was set up in the Beishan area in response to regional insurgence that had become rampant in a declining empire.

Additional specimens in the middle sections of the Fowan cliffs are the more evolved and secularized carvings of the later Song era. The finest includes an assembly of gracefully jeweled bodhisattvas, realistic portraiture of saints, donors, and wrathful guardian kings in cave number 136 (dated 1142–1146). These naturalistic representations were contemporaneous with thirty-one sets of monumental works at the Dafowan (Great Buddha Bend) site of the Baodingshan complex. The Dafowan tableaux of gilded and painted imageries are set on a horseshoe-shaped rock formation 280 meters long, conceived as a life-long project of a Tantric monk named Zhao Zhifeng (b. 1159). They convey messages of esoteric learning interwoven with Huayan, Pure Land, and Ch’an doctrines. Among the images are reminders of karmic retributions, including a diagram explaining the reincarnation process for sentient beings, along with vivid and at times grotesque scenes of sinners’ torments in hell.

Many of the carvings demonstrate unique innovation in organizing carved designs over flat surfaces or in three-
dimensional forms. For example, the genre scenes at cave number 19 are juxtaposed with inscribed texts to underscore the instructive overtone in the narratives. The elongated, oversized figures at cave number 5 are deliberately tilted to maximize perception from below. The half-busts at cave number 11 are used as substitutes for full figures in a kind of artistic cost-effectiveness. And above all, the idiosyncratic natural rock formations at cave number 29 are structurally and iconographically integrated into the sculpted designs to resolve drainage and lighting issues in a deeply cut grotto.

The rock carvings of Dazu County are an expansive and superlative display of the artistic devotion, interpretive skills, and technical ingenuity of the Buddhists of ancient Sichuan.

Amassing foreign debt is one strategy for acquiring capital needed for investment. China’s foreign debt, among the highest worldwide at $331 billion in 2007, has been the impetus for the country’s emergence as an economic power in the twenty-first century.

Foreign (or external) debt is the total amount of money a country owes to foreigners or other countries. Ordinarily a consequence of loans and/or a negative balance of trade, China’s foreign debt in the past has also been the result of huge indemnities forced upon the Qing dynasty (1644–1912) by “unequal treaties” signed with foreign nations.

The impact of foreign debt on China has evolved. During the nineteenth century it devastated Qing authority, in the twentieth century it aided development and modernization projects for the Republic of China, and for Chinese Communist Party’s (CCP) reform-minded leaders such as Deng Xiaoping, Jiang Zemin, and Hu Jintao, it has provided the impetus for China’s emergence as an economic powerhouse in the twenty-first century.

China’s defeat by the British in the First Opium War (1839–1842) introduced the precedent for demands of indemnity by victorious powers. The Treaty of Nanjing (1842) required a 21 million silver dollar indemnity to the British government in addition to 6 million silver dollars paid for the destruction of opium stockpiles. Qing resources, while depleted from an additional 16 million silver dollar indemnity following the Second Opium War (1856–1860), had been sufficient to cover most debts until the start of the First Sino-Japanese War (1894–1895). In preparation for the war, the Qing government borrowed 10 million taels (one ounce silver pieces) from British banks, but after its defeat, the Treaty of Shimonoseki (1895) forced an indemnity of 230 million taels. Loans drawn to pay the Japanese came from British, German, and French banks as well as foreign governments. After the Qing dynasty ended, two thirds of this debt remained outstanding.

The Boxer Rebellion (1900) caused the Chinese government to incur even greater foreign debt. European nations, the United States, and Japan forced the dynasty to pay the costs of the invasion as well as reimburse all foreigners for losses during the uprising. The total “Boxer Indemnity” reached 450 million taels, which the Chinese agreed to pay over the next thirty-nine years at an interest rate of four percent. Collateral for debt obligations came from revenue of the Imperial Maritime Customs, internal revenue taxes, salt taxes, and various sales taxes resulting in a loss of control by Beijing over many of China’s financial resources. In addition, the worldwide decline in silver prices at the turn of the twentieth century decreased the value of the tael relative to international currencies.

The establishment of the Republic of China (ROC) in 1911 brought with it institutional changes including the creation of the Central Bank of China, directly under Guomindang control. Its first manager, T. V. Soong, was also finance minister from 1928 to 1933 and brother-in-law of Generalissimo Chiang Kai-shek. The ROC worked to reduce foreign debt left over from the Qing dynasty through both repayment and loan restructuring.
Debt, Foreign

while simultaneously incurring new debt used to fund development projects. China under the Guomindang (Nationalist Party) never achieved a healthy economy before it faced the devastation of World War II. With the victory of the Chinese Communist Party (CCP) in 1949, China’s government refused liability for foreign debt from previous administrations.

According to The World Factbook, China’s estimated foreign debt for 2006 was US$305.3 billion. By early 2007 it had grown to US$331.56 billion, according to Chinese government sources. Accumulating foreign debt is one strategy of acquiring needed capital for investment, especially for developing countries where standards of living are comparatively low and capital is scarce. Foreign debt is one consequence of foreign direct investment (FDI) in a nation’s industrial development. FDI accelerates economic growth by bringing technology and market access to a developing country. China’s ruling Communist Party has tolerated foreign debt owed to capitalists since the advent of economic reforms associated with the leadership of Premier Deng Xiaoping (1904–1997). Deng’s “Second Communist Revolution,” an economic program based on capitalist principles beginning in 1979, rejected the left-wing socialist policies associated with Mao Zedong and embraced a more pragmatic approach to modernization. One result has been the remarkable growth of China’s economy.

In 1980 the first four SEZs were established along the southeast coastal areas of Shenzhen, Zhuhai, Shantou, and Xiamen. A second group of ten additional coastal cites, the province of Hainan, and the Pudong area of Shanghai were designated SEZs by 1988. Encouraged by the success of the SEZs, between 1984 and 1988 the Chinese government created smaller, more specialized Economic and Technological Development Zones (ETDZ), located along China’s coast or in cities already open for international trade, where high-tech industries are encouraged over more traditional manufacturing firms. By 2006 there were fifty-four national government-sponsored ETDZs, thirty-three located in coastal areas and twenty-one in central China, and hundreds more supported by provincial and municipal authorities throughout China.

A primary purpose of the SEZs and ETDZs is to absorb foreign direct investment. The initial surge of investment in the early 1980s mostly came from Hong Kong, Macao, and Taiwan, whose Chinese expatriates were eager to tap into China’s potential for growth. By the late 1990s, the West and Japan had entered the scene. After China joined the World Trade Organization in 2001, FDI skyrocketed, reaching US$60 billion annually in 2005. Chinese government sources report that the fifty-four ETDZs, totaling a land area of approximately 500 square kilometers, received 15 percent of China’s total FDI for 2006 when over two hundred multinational high-tech companies invested in four hundred industrial projects.

Economists have questioned whether China’s foreign debt should be a concern for the ruling Chinese Communist Party. Many have concluded that it should pose no short- or long-term threat to China’s future development. On the contrary, it reflects an active flow of international capital. Although China’s total foreign debt ranks among the highest worldwide, it is relatively small compared to the gross domestic product (GDP) estimated in 2006 at US$10.17 trillion. Moreover, China’s foreign exchange reserves, in excess of US$800 million, remain higher than the total foreign debt. On the other hand, the politics surrounding foreign debt, FDI, and SEZs are more complicated. The “Fourth Generation” of Communist Party leadership under President Hu Jintao (b. 1942) remains committed to free market economics and capitalism as “temporary” necessities to achieve modernization. Yet they must answer critics within the Party who
decry the inflation, “foreign exploitation,” corruption, and increased stratification in Chinese society that have accompanied phenomenal economic growth. The Communist Party’s official position is that China’s economic achievements should serve as models for other developing nations in the twenty-first century.

June GRASSO

Further Reading
The defense industry is an essential pillar of China’s industrial development and military modernization, producing everything from warships to washing machines. Although it has made significant achievements in structural rearrangement, technological advancement, and weaponry development in recent years, it still faces considerable challenges, such as adapting to a huge labor surplus and the gradual shift from government planning.

Upon its establishment in 1949, the People’s Republic of China was faced with a hostile Western world and came to rely on the Soviet Union for military and technological assistance. This resulted in adopting for China’s defense industry the Soviet organizational model, which dictated that each factory and industrial sector should be as self-sufficient as possible, even at the expense of efficiency. In 1960, the abrupt end of Soviet assistance forced China’s defense research and production to stand alone, adversely affecting the country’s overall industrial development.

Perceived threats from abroad between 1965 and 1971 led to a massive “third-front” (or third-line) construction model, an effort to build a huge self-sufficient industrial base in the remote southwestern and western regions. (The “first front” usually refers to coastal areas, which would be hard to defend; the “second front,” inland from the first front, might have to give way to the “third front,” still farther inland and thus more suitably defended in a protracted war.) Approximately 50 to 55 percent of China’s defense industry was located in provinces such as Sichuan, Shanxi, Hubei, Yunnan, and Guizhou. By 1975, the percentage of domestically manufactured weapons was 71, 75, 89, and 97, respectively, for tanks, aircraft, naval ships, and cannons.

In 1977, after the Cultural Revolution, the defense industry adopted the policy of “combining the military with the civilian” and “using the civilian to support the military” to fulfill the overall goal of economic reform and modernization. Under the joint supervision of the Central Military Commission and the State Council, the Commission of Science, Technology, and Industry for National Defense (COSTIND) was established in 1982 to ensure better coordination in defense-industry leadership. In that year as well, the machine-building ministries were renamed to indicate their functional responsibilities. For example, the Second Machine Building Ministry became the Ministry of Nuclear Industry. The 1980s also witnessed the production of civilian goods by the defense industry, thus involving it in dual functions and profit-making activities.

The significance of high-tech weapons during the Persian Gulf War (1990–91) renewed China’s interest in technological development. In March 1998, COSTIND was headed for the first time by a civilian bureaucrat, a change regarded as an attempt to avoid the military’s heavy-handed interference in the operation of China’s
defense industry. While the General Armaments Department (GAD), newly created within the People’s Liberation Army, oversaw weapons research, the military was expected to pay more for weapons and equipment from COSTIND’s defense factories, due to further involvement in the market economy. On 1 July 1999, corporations in the main defense industrial sectors were split for further specialization. For example, the nuclear industry was divided into the China National Nuclear Corporation and the China Nuclear Engineering and Construction Group Corporation.

**Achievements**

The defense industry’s nearly unrivaled access to supplies and its rarely challenged methods of marketing have gradually responded to market trends following China’s economic reforms. In the 1980s, a shift in emphasis from preparation for war to preservation of peace necessitated the reorganization of the defense industry. Conversion to civilian production mitigated the pain caused by the cuts in military spending and symbolically showed China’s willingness to contribute to global peace. The Chinese government claimed that its military-industrial complex produced and exported $7 billion worth of goods in 1997. Thirty thousand state-owned defense factories engaged in the aerospace, aviation, ordnance, shipbuilding, and nuclear industrial sectors and built everything from warships to washing machines.

While data varies for different sectors, civilian goods in the late 1990s approached 80 percent of the gross output value of China’s defense industry. In 1997, for example, China’s defense industry claimed credit for producing 50 percent of motorcycles and 30 percent of color televisions in the domestic market. The goal was for the defense industry to be increasingly self-sustaining, efficient, and innovative. In addition, loosening state control has given defense factories flexibility in interaction with foreign business communities.

*A Chinese military submarine in Shanghai. Besides making efforts to modernize its naval fleet, China’s defense industry has been working on advanced weapons systems such as cruise missiles and satellite-positioning systems. Photo by Joan Lebold Cohen.*
for dual-use technology acquisition in various category-neutral areas such as information and communications technologies.

Another phenomenon of the 1990s was the formation of big-business conglomerates to link firms vertically and horizontally so that they could participate in economies of scale. One such conglomerate is the China North Industries Corporation, reported in 1997 to have more than three hundred affiliated units with fixed assets of at least $7.5 billion. Another example is China Poly Group, a diversified conglomerate actively engaging in a variety of activities such as tourism, real estate, infrastructure construction, arms exports, and technology acquisition.

Indigenous efforts and access to foreign know-how may enable the defense industry to close technological gaps between China and the world’s other major powers. China’s defense industry has been working on advanced weapons systems such as cruise missiles and satellite-positioning systems. In 1999, China successfully launched and recovered an unmanned spacecraft. As long as China’s economic boom continues and the government increases the budget for military procurement, the defense industry has great potential for growth.

In the 2000s, as a result of the emphasis on selective modernization in key industries based on China’s own assessment of the technological advantage and gradual adoption of market mechanisms, China’s defense industry has indeed begun to show its qualitative achievements in several industrial sectors. In the shipbuilding industry, Chinese destroyers (“Luzhou” class and “Luyang II” class), conventional submarines (e.g., “Song” class and “Yuan” class), and nuclear-fueled attack submarines (e.g., “Shang” class and “Jin” class) built in the 2000s have been more seaworthy and better prepared for surface and undersea warfare, for regional area denial capability (the ability to prevent adversaries from accessing a region), and for the pursuit of long-term objectives of global interest. In addition to the official introduction of the “homemade” J-10 fighter plane and domestically assembled SU-27SKs, China’s aerospace industry rolled out a regional jet, the ARJ21, in 2007. The successful launching and landing of the “Shenzhou 5” spaceship (2003) and “Shenzhou 6” spaceship (2005) demonstrated China’s ability to send astronauts into space. These spaceflights also offered significant insight about China’s missile technology and space-related weapons systems. Meanwhile, China’s nuclear industry has developed and deployed more than ten varieties of ballistic missiles, such as JL-2 (“Julang-2”), submarine-launched missiles (SLBMs), and Dongfeng (DF)-31A ICBMs with an estimated capability of reaching the North American continent. Finally, the joint force of China’s booming information technologies (IT) companies, state research institutes, and ambitious national defense science and technology funding like the National High-tech R&D Program (863 Program, 1986) and the National Basic Research Program (973 Program, 1997) has benefited both the civilian IT sector and the defense industrial establishment. With significant advancement in the production of fiber-optic cable, small-size reconnaissance satellites, and other microelectronic technologies, the military has strengthened Chinese military’s C4ISR (command, control, communication, computer, intelligence, surveillance, and reconnaissance) capability at different levels of the “battle-space” management system. Given China’s rapid economic growth and significant improvement in military equipment and weaponry, a broad overview and sweeping generalization about China’s defense industries would not give a judicious evaluation of their technological capability. Future studies of China’s defense industry will require sector-by-sector examination.

China’s close linkage to the world economy under various trade regimes regulated by the WTO has enabled the defense factory to gain access to a vast array of new civilian dual-use technology spin-offs for the innovation of weapons. Several EU members have found ways to deliver dual-use or “non-lethal” military equipment and parts to China. For instance, tanks and armored vehicles manufactured in China have been mostly powered by German-designed engines manufactured under the licensed production right. The same applies to Chinese submarines, which have adopted German diesel engines and a French sonar system. The policy of “combining the military with the civilian” and “using the civilian to support the military” still persist in the twenty-first century. The Chinese government reported that the sector for civilian goods contributed 78 percent of the revenues of the defense industry in 2007. Meanwhile, China’s White Paper on National Defense issued in 2006 asserted that patent applications by China’s military industrial complex...
Challenges

The legacy of central planning has hurt the economic vitality of China’s defense factories. Many defense plants have found themselves with duplicate production, over-supply, and brain drain to lucrative private enterprises. For the “third-front” defense factories, inconvenient sites and worn-out infrastructure have scared off new investors. Although defense factories have been successful in joint-venture deals with companies like Mercedes-Benz (now Daimler Chrysler), Suzuki, and McDonnell Douglas, by 1998 fewer than six hundred joint ventures had been forged, despite years of courtship.

Overall, the viability of China’s defense industry relies as much on public-policy design, the political will of leaders, and military circumstances as on economic development. Problems like a bloated labor force and ever-increasing costs for technological innovation must be solved. Most important, a defense industry long accustomed to government planning must make a difficult shift to a market mentality in consolidating and rationalizing its industrial layout and operation.

Even with the 1998 structural separation of COSTIND from the military, the image of the defense industry’s symbiotic association with China’s military persists. This mammoth military-industrial complex poses a hindrance to the central authority. Eventual loosening of military control over the defense industry and the stipulation for more transparent arms-transfer procedures seem to be two main tasks for a robust development of the defense industry. The COSTIND’s decision in 2007 on military-enterprises shareholding reform—allowing state-owned companies and qualified foreign investors to acquire or merge military factories—was the latest drive to encourage further civilianization of the defense industry in the market economy. It will be interesting to evaluate how China can achieve a balance between the civilian sector and defense industry and the integration of civilian technology into weaponry R&D as the nation strives to enhance its military capability.
In order to ensure its economic subsistence, the Chinese defense industry needs to rely on income from arms exports. With recipients like Iran and Pakistan, China's aggressive arms-transfer policy made China the eighth largest supplier for the 2002–2006 period. Arms exported by China during this period were estimated at $2.1 billion, approximately 6.6 percent of that of the United States. In carrying out normal arms trade, China stressed its compliance with three basic principles—the enhancement of the self-defense capability of importing countries, noninterference of importing countries, and nonimpairment of regional and global peace, security, and stability. It also promulgated the Law on Control of Guns in 1996, issued regulations on the administration of arms export in 1997, and started to revise arms export regulations in 2002. Nevertheless, its nontransparent practices have frequently led to international accusations and diplomatic disputes for exporting weaponry to some sensitive and unstable areas, such as Sudan, Zimbabwe, and Myanmar in recent years. Establishment of a stronger monitoring mechanism to prohibit its weaponry from transferring to controversial destinations will be a major challenge for the healthy development of China's defense industry in the future.

The Democratic Progressive Party (DPP) of Taiwan was established on 28 September 1986, when martial law was lifted in Taiwan, allowing the formation of political parties.

The origins of the Democratic Progressive Party (DPP) can be traced to two main groups: political prisoners jailed in Taiwan by the Kuomintang (Nationalist Party in Taiwan) government, and exiled dissidents living in Japan and the United States who were members of Taiwan independence movements. Together the two groups were referred to as Dang wai (Outside the [Kuomintang] Party) before they established the DPP.

The DPP's ideology was formulated by the intellectual dissident Peng Ming-min, who drafted a number of manifestos. Peng in 1961 became the young chairman of the Department of Political Science at National Taiwan University. In 1964 Peng was arrested for trying to circulate a manifesto calling for the overthrow of Chiang Kai-shek's exiled government in Taiwan. The main points of his manifesto can be summarized as follows:

1. Historical relations between Taiwan and the People's Republic of China should be minimized.
2. Taiwan is more “modern” than old China.
3. Taiwan’s experience with Japan is more beneficial than its experience with China.
4. Taiwan’s history has mainly been the record of Taiwanese seeking self-determination and self-rule.
5. Taiwan needs a complete change of government.
6. Taiwan’s independence movement is in accordance with the prevailing tendencies in the world.

Taiwan’s leader at that time, Chiang Kai-shek, had, of course, always maintained that Taiwan is a province of China.

In January 1970 Taiwanese dissidents in Japan, Europe, and the United States formed the Taiwan Independence Alliance. The founding members included Tsai Tung-jung, Chang Tsan-hung, Wang Yu-te, and Huang Yu-jen. Growing impatient with Chiang’s authoritarian, one-party rule in Taiwan, they practiced terrorism in an attempt to overthrow Chiang in the 1970s. One example was the assassination attempt on Chiang Kai-shek’s son, Chiang Ching-kuo, the powerful vice premier, by alliance member Huang Wen-hsiung, when Chiang Ching-kuo was visiting New York City on 24 April 1970. Other examples include the attempted murder of Kuomintang representative Teng Yung-kong in Paris on 29 March 1973; sabotage of a power plant in Taiwan, causing minor damage, in January 1976; and the attempted assassination of the Kuomintang governor of Taiwan, Hsieh Tung-min, in October 1976.

After the so-called Kaohsiung Incident (a demonstration by dissidents to commemorate Human Rights Day, 10 December 1979, which led to violence and the alleged
injury of 183 police officers), dissident activists in the United States launched massive attacks against Kuomintang offices in the United States. These attacks included ransacking Kuomintang government offices in Los Angeles (14 December 1979), Seattle (15 December 1979), and Washington, D.C. (19 December 1979), as well as the headquarters of the Kuomintang newspaper Shi Jie Ri Bao (World Journal) in New York City (22 December 1979). Other violent incidents were reported in San Francisco, Chicago, and other major cities with Kuomintang offices. Finally, Li Chiang-lin, the brother-in-law of Kaohsiung city mayor Wang Yu-yun, was murdered in Los Angeles on 28 July 1980. No clear evidence links the DPP directly to any of these terrorist activities. However, many participants were welcomed back to Taiwan during President Chen Shui-bian’s administration (2000–2008).

Major Factions
The DPP is a complex organization with a variety of members and factions. Some are well known, the first being the Formosa Group, which began publishing Formosa Magazine in the 1970s to advocate democracy and Taiwan’s independence as well as to criticize the Kuomintang for its authoritarian rule. Second major is the New Tide Faction, founded by Chou I-jen. Chou helped organize many demonstrations and protests, including large farmers’ protests on 20 May 1988. The New Tide Faction is considered one of the more radical groups within the DPP; many of its members advocated using the concept of the Philippines’ “People’s Power” to overthrow the Kuomintang government. In addition to these two largest factions, numerous small interest groups are centered around various DPP personalities.

However, the Formosa Group members seem to have had the most influence within the DPP in terms of political positions. After Chen Shui-bian was elected president, one prominent former Formosa Group member, Yao Chia-wen, became head of the Examination Yuan, one of the five coequal branches of Taiwan’s government. He had also been elected to Taiwan’s Legislative Yuan in 1992. Another member, Chang Chun-hung, was the DPP’s secretary-general and a member of Taiwan’s Legislature (2000–2005). He had been the editor of two prominent magazines, The Intellectual and Taiwan Political Review, during the 1970s.
Another important member, Huang Hsin-chieh, was, in fact, at one time during the 1960s a member of the Kuomintang. (He left the Kuomintang in 1964 to support the independent candidate Kao Yu-shu for mayor of Taipei.) Huang became chairman of the DPP for three terms from 1988 to 1991. He had been arrested after the Kaohsiung Incident and was sentenced to more than seven years in jail. In the summer of 1997 Huang accepted Kuomintang president Lee Teng-hui’s appointment as vice chairman of the National Unification Council, ironic for a man who in his earlier years had supported Taiwanese independence. Some DPP members called without success for Huang to be expelled from the DPP. He died in 1999 and thus did not live to see the DPP win the presidency of Taiwan.

Former Formosa Group member Hsu Hsin-liang, also a former Kuomintang member, served as the DPP’s chairman from 1996 to 1997. After the Chung Li Incident—a protest that Hsu was involved in and that led to violence in the city of Chung Li in 1977—Hsu fled to the United States, where he established a DPP branch in San Francisco. He returned to Taiwan in 1988. However, he resigned from the DPP in 1999 in order to run for president as an independent. Later he became especially critical of Chen Shui-bian’s policies toward China and led a popular sit-down demonstration in front of the Taiwan presidential office in 2007.

Lin Yi-hsiung, yet another former Formosa Group member, became the eighth chairman of the DPP in 1998. He began his political career in the provincial assembly of Taiwan in 1977 and previously served time in jail for his role in the Kaohsiung Incident. He went into exile in Japan and also lived in both the United Kingdom and the United States before returning to Taiwan in 1989. He ran Chen Shui-bian’s successful presidential campaign in 2000. However, in 2006 he left the DPP and criticized Chen publicly for causing worsening ethnic relations within Taiwan.

**Nationalistic Platform**

In terms of its organizational structure, the DPP followed the Kuomintang model, with power concentrated in the Central Committee, which has a party chairman as its leader. In 1991 it adopted a nationalistic platform proposing a new draft of the Constitution for the renamed “Republic of Taiwan” (as opposed to Republic of China on Taiwan). The DPP has tried to unite its factions around a distinctively Taiwanese identity, using as bait the ultimate goal of an independent Taiwan nation in its efforts to consolidate intraparty debates and disagreements on other political issues.

However, fierce infighting has been a mainstay of the DPP since its founding. For example, during the Third Plenary Conference of the DPP in October 1988 competition by the Formosa and New Tide factions for the position of party chairmanship led to outright violence, including not only quarrels and personal attacks on members’ character but also physical attacks. Although the Formosa Group won the chairmanship, the bitter infighting almost split the DPP. Other serious intraparty squabbling has continued to the present.

The DPP also suffered credibility problems from the outside. Vote-buying, gift-giving, and lavish “free” banquets and all-expenses-paid trips for politicians were widespread during the period of Kuomintang rule in Taiwan (1949–2000). Although the DPP promised voter reform, the DPP, in fact, found itself accused of using many of the same tactics, known as “black gold politics” in Taiwan.

As a result, although at one point the DPP had offered itself as a “fresh” alternative to the corruption of the Kuomintang, the DPP ultimately suffered a loss of voter confidence. In the 2000 election, when Chen Shui-bian was elected to the presidency, he won a mere 39.3 percent of the votes cast—and mostly from traditional DPP strongholds in southern and central Taiwan (Kaohsiung County, Kaohsiung City, Tainan City, Tainan County, Pingtung County, Chiayi City, Chiayi County, Yunlin County, and Changhua County). In fact, the DPP could not have won the presidency if the Kuomintang, in a case of its own infighting, had not split into two parties just before the election: the Kuomintang (with its candidate, former vice president Lien Chan, receiving 23.1 percent of the vote) and the Independent Party (former Taiwan governor James Soong receiving 36.8 percent).

The future strength of the DPP will be dependent on several factors, perhaps most important being able to convince the Taiwanese public that it can improve Taiwan’s economic woes as well as distancing itself from corrupt elements within the party in order to again be able to present itself as a fresh alternative to the Kuomintang.
However, the results of the January 2008 legislative elections suggested the DPP had a long way to go before it would regain its previous popularity.

**Legislators at Large**

The January 2008 legislative election was the first time Taiwan used the “single constituency, two ballots” electoral system. Under this system voters from Taiwan’s seventy-three constituencies cast one vote to choose the candidate they prefer to represent their district in the Legislative Yuan and another vote for their preferred political party, which determines the seat of the so-called legislators at large. This second category of legislator is elected in numbers proportional to the votes that each party wins. However, only parties that win more than 5 percent of all valid ballots can win one of these at-large seats.

The DPP nominated seventy-one candidates for the legislative election, while the Kuomintang nominated seventy-four candidates (not including at-large seats). In addition, 109 candidates from smaller parties plus 42 independent candidates ran for seats. The DPP and the Kuomintang each nominated thirty-four candidates for the legislator-at-large vacancies. Before the election DPP officials hoped to win some fifty district seats, whereas the Kuomintang was expected to win sixty-eight seats. Pundits expected that the scandal-plagued DPP would thus become a minority in the Legislature. However, the actual results ran counter to even the most cynical pundits and the most optimistic Kuomintang predictions.

In fact, the 2008 legislative election proved to be a national referendum on the DPP and Chen Shui-bian. The DPP suffered a resounding defeat, winning a mere 27 seats, whereas the Kuomintang gained 81 seats in the 113-seat Legislative Yuan. Taking responsibility for his party’s defeat, Chen resigned his position as party chair. DPP presidential candidate Frank Hsieh assumed the chairmanship. Analysts felt that the chances for the DPP to win the March presidential election were greatly damaged by this defeat and blamed Chen’s increasingly bellicose and provocative calls for Taiwanese independence in the waning days of his presidency as well as the declining Taiwanese economy as major factors in the DPP’s spectacular defeat. Ma Ying-jeou, the Kuomintang candidate, won the presidential election with a landslide 54.5 percent of the vote, compared to Frank Hsieh’s 41.6 percent.

As of 2006—the last time such figures were made public—the DPP reported that it had a membership of 530,000, made up almost exclusively of Taiwanese with origins in Fujian Province and with only 50 percent paying their party dues. At the same time the Kuomintang reported a membership of 1.1 million. The majority of Taiwanese are independents, with only a small percentage of the remaining citizens officially affiliated with other minor parties.

DENG Xiaoping

Dèng Xiǎopíng 邓小平

1904–1997  Statesman

Deng Xiaoping survived upheavals in the Chinese Communist Party and in his own career to become the paramount leader of China during the 1980s. He helped China become one of the fastest-growing economies in the world, and kickstarted the process of Opening Up and Reform, from 1978 which continues to the present day. After years of autocratic rule under Mao Zedong, Deng moved China in a new economic direction while avoiding a complete rupture with the past.

Deng Xiaoping, eldest son of a prosperous landlord, was born in Paifang village, Sichuan Province in 1904. But by 16, he had already left home. He joined the Communist Party soon after its formal founding in China, in 1923, and, like many of his contemporaries, used a work-study program to go to France, living there for six years, and working, for a period, at the Renault Factory on the outskirts of Paris. He was to spend most of his time here, however, preoccupied with political activism, becoming familiar with many future leaders of the CCP when it came to power. After his stay in France Deng went to Moscow, where he trained further as a political activist and organizer, though he only spent a brief period there.

After working as a Communist Party organizer in southwestern China, Deng moved to the Jiangsi Soviet (1931–1934) to be with Mao Zedong. (The Jiangsi Soviet was an independent government established by Mao and Zhu De, one of the early Red Army military rulers, in Jiangxi Province in southeastern China, after the Guomindang [GMD] led purge of Communist activists in Shanghai in 1927.) During the war against the Japanese from 1937 to 1945, Deng occupied a number of positions as political commissar in the Eight Route Army, one of the Communist’s main forces. He continued his military career during the Civil War against the GMD from 1946 to 1949.

After the civil war Deng’s loyalty to the party was rewarded when he was appointed vice premier. He primarily worked in the ministry of finance, where he formulated economic policy. During a period in the 1950s now widely regarded as one of reconstruction and consolidation, he proved himself as a capable administrator. He worked, in particular, with Liu Shaoqi, and Zhou Enlai, the Chinese Premier from 1949, to improve productivity in the countryside, still the home to the vast majority of Chinese people. But a more assertive role by Mao Zedong in economic policy making from 1957 onwards, followed by a fall out with the USSR, and a purge of intellectuals and rightists, led to the disastrous period of the Great Leap Forward. Deng was to be one of the main leaders, after this policy was admitted to be a mistake, in 1962–1963 in clearing up the mess that had been created, instigating, under President Liu Shaoqi, a series of reforms that looked remarkably like those which reappeared from 1978, a system of farmers having more freedom to grow different kinds of crops; something approaching a primitive agricultural
produce free market even made a brief appearance. But by 1965, Mao’s unease at what he regarded as capitalist tendencies in Liu, and by association in Deng, meant that they were already under a cloud. Deng was one of highest ranking victims of the Cultural Revolution from 1966 onwards, condemned for being a revisionist and capitalist roader, and removed from his position as General Secretary of the Party in 1967. While spared Liu Shaoqi’s grim fate of literally being deprived of medical treatment till he died of cancer, Deng’s son, Deng Pufang, at that time a student at Qinghua University, was thrown from the third story of a building and disabled for life. Deng himself was sent down to the countryside, spending much of the early 1970s in a tractor factory in Jiangsu. But in 1973, after the Tenth Party Congress, and the fall of Mao’s own chosen successor Lin Biao in 1971, Deng was rehabilitated. The Party needed his administrative skills too much, and his great mentor, Zhou Enlai, who was already ill with the cancer that would finally kill him in 1975, needed Deng at his side.

One of the most remarkable features of Deng’s career was his being unique in returning from the political graveyard not once, but twice. Savagely attacked by the group of extreme leftist leaders around Mao during his final days, the Gang of Four, he was removed from office again in 1975. But the death of Mao in 1976, and the decision by the then Chairman of the Party, and Mao’s chosen successor Hua Guofeng to arrest the radical leaders, meant that once more Deng was returned to power, this time making a reappearance during a football match in 1977. He was appointed a Vice Premier the same year, a position he served in until 1982. But despite his lacking the formal titles of leadership, he was, from the 1978 Third Plenum of the Tenth Party Congress, to all intents and purposes the paramount leader of China. He worked, within a group of senior leaders, to steer China away from the ideological and economic excesses of Maoism, dismantling in the early 1980s most of the apparatus of Maoist rule, and centralized economic control, and ushering in a period of bold reform. Such moves had him on the front page of *Time* Magazine twice as Man of the Year. His influence in causing China to liberalize its economy while remaining a Communist Party controlled state are still being worked through to this day, with China, as a direct result of his reforms, becoming one of the world’s major economies.

This era was to end in June 1989 with the Tiananmen Square Incident. Deng was many things, but he remained a faithful Communist Party servant to the last, and he saw the attempts to topple the Party from power as akin
to treason. Even though he had ostensibly retired from all formal positions of power by 1989, including Chair of the Central Military Commission, it is clear from papers reportedly showing the deliberations of the Central Leaders during the period, and subsequently smuggled out of China and published in the West, that Deng's say was decisive in ordering the put down of the demonstrators, many of them students, by the People's Liberation Army (PLA). It was a role for which he was to be internationally condemned, and which changed the rest of the world's attitude towards him.

Deng's final political contribution was to undertake the Southern Tour in 1992, at a time when the liberalization of China's economy, and its openness to foreign investment, looked under threat. His defense of the need to continue and deepen the reforms, which were to culminate in China's entry to the World Trade Organization in 2001, saved China slipping back into a more introspective, isolated position. From 1992 to 1997, Deng was largely invisible, making one final brief public appearance at a Party meeting in 1994, and dying in 1997, only a few months before one of his other major contributions, the successful return of Hong Kong to Chinese sovereignty to the PRC, occurred in June that year. Deng is now called the "chief architect of China's economic reforms" and although his historic contribution is not as dramatic as that of Mao Zedong's, it may well prove to be both more profound in its historic effects, and a great deal longer lived.

Kerry BROWN

Further Reading
In 1992, during a period of economic sluggishness, the eighty-eight-year-old former Chinese Communist Party leader Deng Xiaoping embarked on a Southern Tour, the final large political act of his career. During Deng’s surprise visit to some of the key Special Economic Zones he had established in the early 1980s, he confirmed China’s commitment to economic liberalization and the implementation of radical free market methods.

Former Chinese Communist Party leader Deng Xiaoping’s Southern Tour occurred in the early part of 1992 when Deng, who had retired from all his party and government positions, made an impromptu trip to the special economic zones (SEZs) of Zhuhai, Shenzhen, and Guangzhou in Guangdong Province that he had been instrumental in setting up in the early 1980s. The tour occurred at a time of sluggishness in the Chinese economy and at a time of political uncertainty. Because Deng was by far the most influential political figure still alive from his generation, the symbolic impact of his tour was immense, and one can claim that it revitalized China’s second phase of reform and opening up, which had begun in 1978 and 1979. This was to be Deng’s last major contribution to China’s development, and he later would die after five years of political inactivity.

The Southern Tour took place at a difficult time for China and was provoked by several problems. Although China had enjoyed a decade of good growth in the 1980s, implementing radical market-based reforms into its economy, a combination of political stasis, corruption, and inflation had led to the disturbances in 1989 and to the June 4th Massacres, in which crack troops from the People’s Liberation Army (PLA) had entered Tiananmen Square after several weeks of student and popular protest and had killed many hundreds of demonstrators. That this tragedy had taken place before the world’s eyes and at a time shortly before uprisings in eastern Europe led to the fall of the Berlin Wall and the toppling of dictators such as Romania’s Ceausescu only added to the opprobrium pulled down on the Chinese government’s head. Foreign companies withdrew, political leaders from Europe and the United States condemned what had happened, and China found itself edging closer to the isolationism that it had experienced during the final decades of Mao Zedong’s rule up to 1976.

Chinese leaders, under first Hu Yaobang and then Zhao Ziyang, both general secretaries of the Communist Party, had supported research in the mid-1980s into forms of political reform, some of them modeled on north European social democratic democracies such as Sweden and Denmark. However, the consensus was that moves in this direction were too soon and too unpredictable. China, it was argued, needed firm, central leadership to avoid slipping back into the chaos it had experienced in the period before the founding of the People’s Republic of China (PRC) in 1949 and the Cultural Revolution (1966–1976). Foreign observers were sufficiently excited by the possibility of seeing radical political reform in China to match the startling economic changes. Deng Xiaoping even became
Time magazine’s “Man of the Year” (1985) during the decade and was seen, despite all the evidence to the contrary, as a closet democrat, a man like Mikhail Gorbachev of the USSR (himself a man with whom—in the words of British prime minister Margaret Thatcher—“we could do business”). The events of June 1989 effectively rid people of their illusions. Deng was to starkly state immediately after the crushing of the student demonstrators that although there was an inevitability about what had happened, in view of the national and international context, the party would not compromise in its aim to implement economic reforms but rather would stand fast to the monopoly on power of the CCP. This harsh response, however, made many observers believe that China would turn its back again on economic reform and close its doors. Beginning at the end of 1989 many foreign companies withdrew from China, and the amounts of trade decreased.

**Special Economic Zones**

The signs that the central government was still deeply committed to continuing the path it had followed up to 1989, albeit in a slightly modified form, came in 1990 when Shanghai was unexpectedly added to the five SEZs that already existed, meaning that it would enjoy preferential policies in attracting and accommodating foreign direct investment. At about this time Deng admitted that not making Shanghai, perhaps the most entrepreneurial and capitalist of all China’s major cities, an SEZ at the same time as the others in the early 1980s had been a mistake. Also in 1990 company and investment laws were passed to provide greater protection for foreigners. These laws were passed at the same time as the United States, under President George H. W. Bush, finally decided against imposing sanctions on China for the events of 1989 but instead put in place a military embargo, allowing other trade contact to continue.

Even so, 1990 and 1991 brought only sluggish growth. Foreign direct investment dipped. The new leadership of the party was nervous and uncertain under Jiang Zemin, previously party secretary of Shanghai and then pulled up to replace the felled Zhao Ziyang, who was to take the majority of the blame for the events of June 1989. Jiang lacked any real power base in the party and had been as surprised by his elevation as those around him. However, despite having reservations, Deng, who was key in the decision, had few alternatives.

Deng’s position in the late 1980s and early 1990s was unusual. In 1989 he had resigned from his last formal position of power, that of chair of the Central Military Commission. Beyond being president of the Chinese Bridge Playing Association (he was a world-class bridge player), he held no public positions whatsoever. However, as the “chief architect of the reform process,” as he was labeled in internal Chinese parlance, and as “paramount leader,” as he was labeled outside of China, Deng clearly wielded final say on all important strategic matters. Without Deng’s support important policies would not be implemented nor get passed through the newly constructed machinery of government, nor would personnel changes of any significance be made. Deng also was held in immense esteem by the PLA, who in June 1989 had proved itself once more the final trump in any power struggle or conflict.

Although barely visible during 1990 and 1991, Deng had commented on his frustration with the slowness of the reforms and on the fact that they had encountered a lean period. He had commented in the late 1980s that he was retiring to let the younger generation develop and did not intend to interfere. In doing so he must have had in mind the final period of Maoist rule, when the aging and increasingly erratic Mao had fiercely held on to power, dragging the country deeper and deeper into crisis and poverty. However, in China such well-intended abnegation was easier to say than to do. By late 1991 it was clear that there was policy drift at the top of the central government; no clear messages were getting out about the need to continue deepening reform; and no signs were clear to the rest of the world that China was putting June 1989 behind it and now ready to move forward.

Deng’s Southern Tour, which occurred during January and into February 1992, can be interpreted as belonging to the tradition of Chinese leaders going above the heads of government to appeal directly to the people. Mao himself had frequently waged campaigns in which he had circumvented the bureaucracy and even the party in order to speak directly to the people. At the age of eighty-eight, therefore, and with his immense prestige, Deng was willing to speak directly one final time. He was also able to reach a wide audience through television and radio coverage and print media. News of his surprise appearance in southern China was widely covered in the international
Deng Xiaoping’s Southern Tour

media. The term in Chinese for his visit, *nan xun*, gave his visit an almost imperial flavor because it was a term used in the past about imperial visits to Chinese provinces. In Shenzhen and Zhuhai Deng was able to appear at the places most closely identified with the economic reforms of the last decade, one facing Hong Kong and the other Macau, both places for which he had negotiated successful returns to Chinese sovereignty.

Deng’s message on the tour was simple and repeated in each of the places he visited: China’s continuing opening up and reform were inevitable and could not be stopped. Those in the party who blamed the events of 1989 on foreign influences and ideas that had polluted the atmosphere of China because of the opening-up policy were wrong. Foreign investment and foreign enterprise were needed in China because they brought badly needed technology and expertise. Without them China’s attempts to modernize were blighted. Problems would arise from time to time, but a government that did not deliver prosperity to its people was no good. The Communist Party would continue to support the reform process and develop socialism with Chinese characteristics, a form of Marxism-Leninism adapted and suitable for China’s specific circumstances. Foreign companies were encouraged to continue coming to China and were reassured that as long as they complied by the rules and paid the appropriate taxes, China would be a safe place for them to work.

**From Words to Deeds**

The impact of Deng’s words was almost immediate. Although China had enjoyed reasonable levels of foreign direct investment in the years leading up to this time, the real floodgates opened in 1992, with foreign direct investment climbing year after year to the total of almost $700 billion at the end of 2006. A surge in Hong Kong, Taiwanese, and Japanese investment lay behind this increase, with U.S. and European investment closely following. Deng’s impromptu remarks in each of the cities he had visited on his tour were immediately printed and distributed to party members throughout China. China continued its negotiations to enter the World Trade Organization (it succeeded in 2000) and made two attempts (the first failing, the second succeeding) to host the Olympics. Although groups broadly described as “new leftists” continued to question China’s reform path and the need for such heavy foreign involvement, in the decade that followed Deng’s intervention made it much easier for supporters such as Zhu Rongji or Jiang Zemin to justify what they were doing. It also made crystal clear that economic reform did not mean political reform and that the situation would stay that way for the foreseeable future. Overheating of the economy in the years immediately after 1992, along with the pain caused by state-owned enterprise reform and the mass layoffs this caused, was dealt with by the central government in such a way that major turbulence and disruption were avoided.

Deng’s international image had been badly tarnished by the events of 1989. However, what he had achieved as an old man in 1992 went some way toward rehabilitating his image and reminding people inside and outside China of why he had been so important in China’s development. He made few appearances after 1992 and no more interjections (beyond indicating that he regarded Hu Jintao as a possible successor to Jiang Zemin, a succession that was to happen in 2002–2003). His death in 1997 was marked by genuine grief. The Southern Tour was Deng’s final return to political activity after several falls from power throughout his lifetime.

Although this return to power was not as spectacular as the previous ones, it was, in impact, as great, if not greater, and contributed to the immense economic success of China in the twenty-first century.

Development Zones
Kāifāqū 开发区

Development zones—special areas for international trade and investment, export processing, and technology evolution—are thriving and driving China’s economy. Administered locally, development zones are the pride and, in many cases, the future of a growing number of Chinese townships, small cities, and counties as they jump on the economic bandwagon.

China created its first development zones in 1984. Their formation intensified the country’s open-door policy and engagement with the outside world. By 1988 China had designated fourteen development zones: Dalian, Qinhuangdao, Ningbo, Qingdao, Yantai, Zhanjiang, Guangzhou, Tianjin, Nantong, Lianyungang, Fuzhou, Minxing, Hongqiao, and Caohejing. All fourteen zones were near coastal cities and placed major emphasis on export processing, technology development, and foreign investment. Operating with tax incentives and entitlements, such as modern infrastructure and high-standard business services, development zones are growing and helping drive the economy.

Concept and Characteristics

The Chinese did not invent the development zone, but they have made better use of the concept than most countries have. Development zones were operating in South America in the early twentieth century. They became more common after World War II in such forms as free ports, free-trade zone, export-processing zones, science and industry parks, and border trade zones. One purpose of these zones was to help rebuild national economies destroyed by war. China modeled its development zones on other countries’ experiences, treating the zones as a new means to open to the outside world. China’s goal was to create an attractive business environment to encourage foreign investment, joint ventures, and technology development and transfer, and to learn advanced management skills.

China’s development zones are similar to its special economic zones (SEZs) but have distinct features. SEZs are relatively independent; their administrative status is equivalent to that of a province’s. Development zones, by contrast, are administered by local governments through a special committee. While SEZs are encouraged to develop into diversified economic structures, development zones focus on exporting, technology, or other special sectors. In SEZs all types of businesses enjoy tax incentives; in development zones tax incentives are offered only for investment in industry and technology or in other designated sectors.

Development zones are usually in or close to areas with well-developed industrial foundations, an advanced economy, and easy access to transport networks. Economic and technological development zones and tax-free zones are normally established in coastal cities and ports, which are advantageous locations for these sectors. Border cooperative zones operate in inland border trade areas. High-tech-development zones are in large or medium-sized cities throughout the country.
Creation and Growth

In 1983 China opened up fourteen coastal cities. In late 1984 and early 1985, the government designated eleven development zones in eleven coastal cities. Two development zones were established in Shanghai in 1986 and another in 1988. During this start-up stage, from 1984 to 1988, the main tasks were to establish an administrative committee to oversee the development zones, as well as the establishment of the Economic and Technological Development Corporation; plan the development zones; prepare and create regulations and policies relating to the development zones; and construct the physical infrastructure.

Different types of development zones have been established since the original type. The first high-tech-development zone was established in Beijing in 1988. Tax-free zones were created in 1990. Development zones have undergone rapid growth, boosted by Deng Xiaoping’s (1904–1997) call in 1992 for further opening up of China’s economy. Since then even small cities, counties, and townships have set up their own development zones.

Achievements and Problems

Although development zones occupy only 0.004 percent of land in China, they account for about 10 percent of the total national foreign investment. More than two hundred international corporations have invested in China’s development zones, effectively advancing technology development and facilitating national economic restructuring. In most development zones, more than 60 percent of the industrial projects are high-tech or new technology projects.

Development zones have helped create rapid growth and high productivity. The gross industrial product in the first thirteen development zones increased about 450 times within their first ten years and had grown to 135 billion yuan (about $20 billion) in 1996.

Some of the early problems associated with development zones included a lack of strategic coordination and effective control in their development. For example, 1992 saw the sudden creation of more than two thousand new development zones, more than twenty times the number created before 1992. Among these, only 1.1 percent were approved by state, province, or city governments. A number of counties, small cities, and townships also established development zones, resulting in uncontrolled expansion and the occupation of some 33 billion square meters (about 13,000 square miles) of land, of which 80 percent was arable.

Change and Challenge

Development zones have played a leading role in China’s economic growth since the 1980s. All types of development zones have generated the highest output in their areas and have become the economic engines for various cities and entire regions. In 2006, 68 percent of the gross domestic produce and 87 percent of the exports in China came from development zones at different levels. But as the global economy began to change in 2008, so did China’s development zones.

Tax standardization for both domestic and foreign enterprises, the strength of the yuan, a tight monetary policy, and stricter land-use policies have all had a direct impact on the big and small enterprises within the zones. Land use, in particular, is a major issue, as more land is needed to grow food for China’s rapidly increasing population and as many development zones have been hard on the land. Some economists believe that the first development zones, although having lived up to their promise, have run their course and a new model is needed to meet the new challenges. The new development zones will have to focus on industrial upgrades and technology, with an eye to environmental concerns.

Ding Ling was one of China’s most popular and productive authors of the twentieth century. She wrote short stories, novels, essays, plays, and parables, totaling more than three hundred works. Her major works described the best and worst of Chinese society. Always popular with the reading public, Ding was both praised and vilified by government leaders during her long lifetime.

Ding Ling, the pen name of Jiang Bingzhi, was born on 12 October 1904 in Linli, Hunan Province. As author and activist, Ding always maintained a deep interest in the struggles of Chinese women. One of the country’s most productive and popular authors of the twentieth century, she was the first writer to portray women liberating themselves in Chinese society. Her collection of short stories, Miss Sophie’s Diary and Other Stories, published in 1927, featured unorthodox young women questioning the feudal attitudes of China, in particular rules governing women’s behavior. Some of her short works are available under a collection titled I Myself Am a Woman: Selected Writings of Ding Ling.

Later, in the 1930s, she switched to novels and became one of the leaders of the new school of leftist literature. One of her best known novels (although unfinished) is Mother. This book is based on her mother’s experiences as a widow raising three children. Ding’s mother was an educator and activist and Ding’s main role model.

Ding’s writings and activism often got her in trouble with the leaders of China. Shortly after joining the Chinese Communist Party (CCP) in 1932, she was arrested by the Guomindang (Nationalist Party) government and held in detention for three years. Her husband Hu Yepin, a poet and communist activist, was killed by the Guomindang in 1931.

In 1936 she traveled to Yan’an, the headquarters of the CCP at that time. There she published the well-known essay “Thoughts on the March 8 Festival (Women’s Day),” in which she examined women’s situation and sharply criticized discrimination against them. This made her a target of the Communist Party’s Yanan Forum on Literature and Art in 1942, part of a spirited effort by the party to bring Marxist ideas to the Chinese masses.

Even though she held senior official positions for several years after the establishment of the People’s Republic of China, she was once again criticized in 1955, and her novels and essays were banned. From then until the end of the Cultural Revolution in 1976, she was either in jail or in labor camps. Nevertheless, she continued to write.

In 1981 Ding Ling, along with other prominent Chinese authors, were allowed to participate in the International Writing Center at the University of Iowa. For four months she wrote, lectured, and met with writers from the United States and other countries. This helped to cement her international reputation.
Despite suffering from diabetes and other ailments, Ding Ling continued writing up to her death in Shanxi Province on 4 March 1986.

Disability
Cánzhàng 残障

Approximately 83 million individuals in China have one or more disabilities. Much progress has taken place over the past thirty years for China’s disabled population, with the establishment of organizations and networks as well as mechanisms of operation. While individuals with disabilities have started receiving more respect than in the past, services and resources need to be expanded.

In China, individuals said to have disabilities are those who have suffered since birth or who have subsequently completely or partially lost physical, mental, or physiological and psychological functions, which therefore prevents them from performing some or all daily activities normally. Disabilities in China are currently categorized as sensory impairments (seeing, hearing, and speaking impairments), physical impairments, cognitive impairments, and psychological and mental impairments; some individuals have multiple impairments.

Development of Services
Development of services to individuals with disabilities can be roughly divided into three stages: The first stage (1949–1966), from the founding of the People’s Republic of China (PRC) to the beginning of the Cultural Revolution, established a system for administering and managing matters such as housing, education, employment, and rehabilitation services for individuals with disabilities. For example, after the founding of PRC in 1949, local governments adopted most homeless individuals with disabilities and housed them in orphanages, social-welfare institutions, or nursing homes, depending on their age and degree of disability. Those who were living in urban areas and who were still capable of working were employed at community and neighborhood workshops and welfare factories (*fu li gong chang* 福利工厂). Welfare factories are organizations that employ specifically individuals with disabilities or individuals who are unable to seek competitive employment as their counterparts in the society. These organizations in return receive government subsidies. Individuals in rural areas were enrolled in collaborative groups (*hu zhu zu* 互助组 *he zuo she* 合作社) in their villages. These groups were administrative units in the 1950s and 1960s in the rural communities that managed daily farming and other activities. The head of these units was usually elected by local villagers in the early days and later was appointed by the supervising government. During this period the second generation of the Chinese version of the Braille system was designed and implemented (the first generation was created in the late nineteenth century), special schools for people with hearing and speaking impairments increased from 41 before 1949 to 266 by 1966, and students receiving special education increased from two thousand to twenty-three thousand at the same time. In addition, associations were formed for individuals who had no or low vision, hearing impairments, and speaking impairments. Government agencies for rehabilitation
services were set up as well as, special sports events, national conferences on disabilities, and a journal for blind or vision-impaired individuals.

During the ten years of the Cultural Revolution (1966–1976), the whole country was in chaos and facilities that provided services to individuals with disabilities stopped functioning.

Since 1978 rapid economic reform has brought profound social changes to China, leading to tremendous changes for people with disabilities. Individuals with disabilities are no longer considered useless or a burden to the family or society; they have been recognized for their creativity and spiritual capabilities. The public has shown more understanding, acceptance, and, most of all, respect for individuals with disabilities. At the same time, individuals with disabilities have had more opportunities to show their abilities and their unique and valuable contributions to society. A series of milestone laws and regulations has been passed since 1985 to guarantee the rights of disabled individuals regarding education, employment, housing, accessibility, and services. The creation of the China Disabled Persons’ Federation (CDPF) in 1988 united associations designated for different disabilities; CDPF became the most powerful voice for addressing the interests of individuals with disabilities and for providing them with program management and services.

Deng Pufang, the son of Deng Xiaoping (1904–1997), China’s leader of economic reform, deserves a special place in the history of the development of disability programs due to his irreplaceable impact on the awareness of disabilities and his contributions to the cause of improving the well-being of the disability population in China. Because of his father, Deng junior was persecuted in 1968 during the Cultural Revolution when he was still a physics student at Beijing University and suffered injuries that left him paralyzed from the chest down. Since the economic reform, he used his special family influence and tax waiver benefits to establish the largest private enterprise of disabilities in China and attracted billions of dollars investment. In 1988, he assumed the first chairmanship of CDPF and stayed in the position for consecutive four terms until November 2008. During his twenty-year long tenure Deng made full use of his special status to promote services and legal rights for individuals with disabilities. Under Deng’s leadership, CDPF has extended and expanded significantly its services and assistance that benefited millions of individuals with disabilities. Meanwhile, the organization also established a national network that can provide effective management and perform advocacy functions for the individuals with disabilities.

Current Demographics

Because of the work of Deng Pufang and his colleagues, disability programs have flourished nationwide along with economic reform in China. According to the preliminary results of the Second National Survey on Disabled Persons (2006), China’s population of people with disabilities was estimated as 82.96 million, which was 6.3 percent of the total population, based on a 2005 census of 1,309.48 million people in China. Out of this

A blind man plays an erhu on the streets of Beijing. A girl, also blind, sits beside him. PHOTO BY TOM CHRISTENSEN
population with disabilities, individuals with physical impairments made up the largest group (29.1 percent), followed by those with hearing impairments (24.2 percent), visual impairments (14.9 percent), mental or psychological impairments (7.4 percent), cognitive impairments (6.7 percent), and speech impairments (1.5 percent). Individuals with multiple impairments accounted for 16.3 percent.

Among these 82.96 million individuals with disabilities, 51.5 percent were males, and 48.5 percent were females. In terms of age, 4.7 percent of the population was under fourteen (3.87 million), 42.1 percent between the ages of fifteen and fifty-nine (34.93 million), and the remaining 53.2 percent sixty or more years old (44.16 million). Of individuals age fifteen and above, 48.11 million (60.8 percent) were married, 9.82 million (12.4 percent) were unmarried, and 21.16 million (26.8 percent) were divorced or widowed. Regarding place of residence, about a quarter of the disabled population lived in urban areas and three quarters in rural areas. Considering the degree of disability, less than a third (29.6 percent) of the population had first- or second-degree disabilities (more significant) and the majority (70 percent) had third- or fourth-degree disabilities (less significant).

The education levels for the population with disabilities were not proportional to the levels in the general population. Out of the 82.96 million individuals with disabilities, only 1.1 percent received college education, 4.9 percent obtained high school education, 15 percent had junior high education, and about 31.8 percent of the population had only elementary education. Illiteracy was very high, about 43.3 percent.

The 2006 survey estimated that 2.46 million children with disabilities (slightly less than 3 percent of the total population with disabilities) were of school age (ages six to fourteen). Statistics for children receiving education by disability type are presented in table 1.

Regarding employment, in urban areas 2.97 million disabled individuals were employed, and 4.7 million were not; 2.75 million (13.3 percent of total individuals with disabilities in urban areas) received minimum social security benefits, averaging 4,864 yuan a person. In rural areas 3.19 million received minimum social security benefits, averaging 2,260 yuan a person, with 13 percent of this subpopulation having an average annual income below 683 yuan.

### Services and Outcomes

Programs for disabled individuals in China have been working in the following nine areas of services over the past thirty years: rehabilitation, education, employment and social security, alleviation of poverty, cultural and sports activities, social support, protection of rights, development of information network, and organization construction. According to the report on the implementation of China’s tenth five-year work plan in disability, by 2005 China had 1,662 special education schools, more than 2,700 special classes in regular schools, 3,250 vocational education institutions, 3,048 employment agencies, more than 19,000 rehabilitation service centers, and 2,574 law service centers. As for delivery of services to individuals with disabilities, 6.42 million received rehabilitation services to different degrees, 80 percent of children were enrolled in schools (this percent refers to the individuals who received services), close to 0.6 million received vocational education, 7 million rural individuals came out of poverty, and 5.16 million urban individuals continued to have their basic needs met. In addition, individuals with disabilities have achieved outstanding results in cultural and sports activities in the world.
At the fifth China Disabled Persons’ Federation national congress in November 2008, Deng Pufang updated the figures by reporting that, according to China Daily, the country has 1,655 special education schools, 3,127 employment agencies, and 5,998 law service stops (维权岗, local offices that help individuals with disabilities to protect their rights.) for the physically disabled.

The remarkable performance of Chinese athletes with disabilities in both the 2007 Shanghai Special Olympics and the 2008 Beijing Paralympics demonstrated convincingly the progress of disability programs in China. For the 2008 Beijing Paralympics, a total of 332 Chinese athletes participated in all twenty fields and won eighty-nine gold, seventy silver, and fifty-two bronze medals. The success has motivated millions of individuals with disabilities in China.

### Challenges

The population of disabilities has been widely treated with bias in employment, education, communication and social life. Their average living standard has been below that of the general public. They have been considered one of the disadvantaged groups in China for many years. While great achievements and progresses have been made since 1949, individuals with disabilities still remain one of the most disadvantaged populations in China due to lack of resources and escalating competition in the labor market. For example, the four most wanted services by individuals with disabilities have not been universally delivered. (See table 2.)

How to narrow the gap between the population with disabilities and the general population, how to overcome the barriers to rehabilitation, education, accessibility, communication, and employment; and how to improve the mechanism that helps individuals with disabilities merge into the mainstream are serious challenges that the Chinese government faces in the years to come.

Deng Pufang (son of Deng Xiaoping, who was crippled by the Red Guards) meeting with Ted Kennedy, Jr., then a lawyer advocating for disability rights. Deng Pufang is known for his work protecting the disabled; in 1984 he established the China Welfare Fund for the Disabled. Then he founded and became the chairman of the China Disabled Persons’ Federation in 1988. In 2003, he was awarded the United Nations Human Rights prize for his work. PHOTO BY GEORGE TAME.

Disasters in China, whether natural or man-made, are amplified in magnitude by the size and density of its population. Historically, the Chinese have been reticent to publicize the seriousness and scope of its disasters. Contemporary China is taking greater steps to minimize the effects of disasters through stringent building and environmental regulations while accepting greater amounts of external aid and expert advice.

Described as "a land of floods, fault lines, and food crises," China is certainly not immune to disasters. A quick glance at any top-ten list of historical disasters will reveal China's unfortunate prominence. Whether it is flooding along the Huang (Yellow) or Yangzi (Chang) rivers, earthquakes in Tangshan or Shaanxi, a dam failure at Banqiao, or an industrial accident at Jilin, China has had its share of devastating disasters both natural and human caused. Because of China's geology, geography, and huge population, the country's disasters often take on monumental proportions.

China is also renowned for its secretiveness, which means that often the extent of disasters is unknown as the Chinese government is reluctant to disclose details. Chinese officials, dating far back into history, have craved order, fearing that situations could spin into chaos and result in unintended consequences, especially for political leaders. In 1351 and 1644, the Chinese people rose in revolt against their leaders in the face of severe famine and floods, resulting in the establishment of two of China's greatest dynasties, the Ming and Qing. In the past, Chinese officials, both public and private, have also attempted to deny or cover up disasters, especially the human-caused variety, as was the case following the Jilin chemical plant explosion in 2005. Nevertheless, as the frequency and scope of disasters have increased in the past century, China has had to increasingly allow for greater international scrutiny and assistance not only in its attempts to predict or minimize disasters but also to clean up from them.

Natural Disasters

1556 Shaanxi Earthquake

In the early morning of 23 January 1556, Hua County in Shaanxi Province became the epicenter of an earthquake estimated to have measured 8.0–8.3 on the Richter scale. The quake was so strong that observers witnessed plateaus and plains cracking, mountains moving, trees becoming inverted, hills rising, and valleys sinking. Some witnesses reported that rivers changed direction. Schools, temples, city walls, and government buildings collapsed. The eight provinces surrounding the epicenter were most devastated; however, the effects of the quake were felt in a hundred counties across ten provinces. The stricken area experienced three to five aftershocks during the next
six months, although other reports suggest that the after- 
shocks lingered for nearly three years.

Occurring in a densely populated area with poorly 
constructed houses, the Shaanxi earthquake wreaked 
destruction over an area of 804 square kilometers. Few 
people survived in the 400-square-mile area from the 
epicenter (estimates suggest that three-quarters of the 
people at the epicenter perished). People died not only 
from the quake itself but also from resultant floods, land-
slides, lootings, and from fires that burned for days. Al-
though the method of counting the dead and injured was 
not reliable, estimates put the dead at 830,000, making 
the Shaanxi earthquake the most destructive quake in 
history and the third-most destructive natural disaster in 
history. Many people lived outdoors and were killed by 
falling debris. Many people died when landslides caused 
the collapse of the loess cave dwellings (yaodongs) in the 
Shensi Cliffs (loess is a grayish silt/clay that is not strong 
enough to resist such a powerful movement of the earth). 
People were buried alive.

The best description of the quake was written by a wit-
tness, the scholar Qin Keda, in A Chronicle of the Violent 
Earthquake. Keda not only paints a despairing picture 
of the catastrophe but also provides the earliest sugges-
tions of how people should react to an earthquake— 
suggestions still stressed today. Keda recommended that 
people find a place inside a dwelling or other structure 
that is sturdy and safe so that nothing can fall on them 
and remain indoors after the initial jolt to avoid injury 
from aftershocks.

In the aftermath of the quake people began to rebuild 
their homes, but the construction materials used were 
bamboo and wood—materials that are more flexible and 
better able to withstand the jarring movements of an 
earthquake and that are also less likely to collapse. And 
if they do collapse, they are less dangerous to people who 
are struck by them.

1876 North China Famine

Beginning in 1876 and lasting three years, the worst natu-
ral famine in world history struck five provinces in north 
China: Shantung, Chihli, Honan, Shansi, and Shensi. The 
famine had been preceded by a drought in the previous two 
years and was aggravated by the depletion of grain stocks 
and the provision of grain to the Qing dynasty (1644–1912) 
military campaigns of the 1860s and 1870s, reducing the 
peasants’ ability to deal with drought when it struck.

Experts estimate that in China famine occurred in 
at least one province every year from 108 BCE to 1911 CE. 
Often the famines occurred because of drought or flood. 
This pattern has caused China to be known as the “Land 
of Famine.” The frequent occurrences of famine have 
placed a tremendous burden on the Chinese state, whose 
historical role has been to provide for the general welfare 
of the populace. The state goes to great lengths to promote 
agricultural production while ensuring that the people 
possess both the tools and skills necessary to till the land. 
Unlike the more modern mind-set regarding population 
size, the Chinese have never viewed population growth 
as an impediment to development but rather as a sign of 
prosperity. The Chinese state’s inability to maintain the 
basic needs of the people generally has indicated a failure 
of its fundamental nature.

The Chinese often refer to disasters as tianzai (heav-
enly calamities) except for famine, which is referred to as 
zaihuang, a disaster that results from human interactions 
with nature. A combination of disasters—for example, 
flood-famine, drought-famine—is often interpreted by 
the Chinese to mean that the state has lost the Mandate 
of Heaven.

Compounding the severity of the 1876 famine was the 
rise of European imperialism and its negative effects 
on the Chinese state and agriculture as well as the Qing 
dynasty’s limited response to the unfolding disaster. For 
centuries the Chinese economy had been built on an “in-
dependent peasant economy and smallholder agriculture 
along with exchanges within local markets,” which was 
dermined by “imperial bankruptcy and British aggres-
sions” (Raghavan 2008), not to mention the substitution 
of grain production for opium production, which caused 
food prices to soar. The Qing dynasty was further preoc-
cupied “with international issues [especially European 
encroachment], rising military costs, local disturbances 
in many provinces and the high cost of transferring grain 
via the backward transport system” (Myers 1985, 370) of 
the country. Additionally, the earlier Taiping Rebellion 
(1850–1864) had destroyed some of China’s best farmlands, 
so it is no surprise that the Chinese people regarded 
the series of events leading to the great famine as “Heav-
en’s anger at human misdeeds as the underlying cause” of 
the famine (Edgerton-Tarpley, 2004).
“Heaven’s Anger”
Indeed, “Heaven’s anger” was ferocious. During a two-year period the famine claimed nearly twelve thousand lives per day. The three-year drought affected 100 million people, killing 9–13 million (although official Chinese estimates placed the death toll nearer 20 million). In the five provinces affected, with a total population of 108 million, some areas reported death rates of 60–90 percent. Although the major cause of the famine was drought, the major cause of death was not starvation but rather epidemic disease, particularly cholera and malaria. In a sad irony, the outbreak of disease coincided with improving drought conditions.

The famine challenged the Qing dynasty’s ability to provide for the welfare of its people, methods of relief for famine victims, and long-held Confucian values. At the national level, the government issued little news of the famine and tried to cover up its existence. The government went so far as to forbid foreigners from entering the affected area for the duration of the famine. Nonetheless, foreign accounts and commentaries, made available through translations in local papers, detailed China’s inability to assist its own citizens. These accounts resulted in a growing sense among the Chinese that their civilization, long believed to be at the center of the universe, had failed.

The Qing dynasty had established in the eighteenth century a famine relief system that worked quite well and underpinned the legitimacy of the Qing dynasty. However, by the nineteenth century people began to sense that the government was no longer capable of caring for its people because of the continuous cycles of flood and famine. Adding to the government’s problems in providing relief were bad roads, poor transportation systems, insufficient amounts of relief aid, and corruption. The government also resorted to using the army to massacre peasants attempting to flee rural areas to cities in order to escape the famine. As the government dealt with external preoccupations, the famine was worsened by “the rapid decline in state capacity and popular welfare followed in lockstep with the Chinese Empire’s forced ‘opening’ to modernity by Britain and other countries” (Raghavan, 2). Aid for famine victims would come from the outside and from distant Chinese elites.

However, local leaders resisted outside aid, convinced that such aid and the presence of foreigners to deliver such aid would further undermine government legitimacy, leading to the possibility of rebellion. Nonetheless, foreigners in the affected areas began to organize relief efforts. Those efforts began in London in 1878 and represented the first attempt by foreigners to assist the Chinese people afflicted by famine. Guo Songtao, Chinese ambassador to Great Britain, acknowledged those efforts in a short article published in The Times of London. Foreign missionaries, most notably Timothy Richard of the Baptist Missionary Society, used the relief systems to proselytize and spread the gospel. Foreign relief activity was crucial to establishing the China Famine Relief Fund Committee, designed not only to provide relief in times of famine but also to address the underlying issues of rural poverty and lack of modernization in China.

First Broad-Based Aid Campaign
The relief efforts were the first broad-based public campaign to raise money and provide relief to victims of famine in China. The campaign spurred on foreigners and local elites in China to assist the victims. Criticizing the imperial government’s efforts, local elites assisted others outside of their local territories, putting them in direct competition with foreign efforts. The intersection of relief efforts by a myriad of competing groups in Chinese society—for example, the government, elites, and foreigners—provided an impetus for the emergence of modern Chinese nationalism. However, that nationalism clashed with historical Confucian values.

Extreme disasters, such as prolonged famine, challenge long-held value systems. Traditional Chinese Confucian values, especially the notions of filial piety and female chastity, strained under the immense suffering. As Kathryn Edgerton-Tarpley has pointed out, the famine challenged the “definitions of moral & immoral responses” (Edgerton-Tarpley 2008, 121) to disaster. The role of women in Chinese society was either upended or confirmed in the affected areas. Knowledge of people starving, people committing suicide, women selling themselves to obtain money to purchase food, and people sacrificing wives and children for older mothers (and older female in-laws) strained social relationships. Edgerton-Tarpley cites an example of “Shanghai’s merchants and elites using female images of famine to motivate the Chinese to rescue women in order to prevent the Chinese from national humiliation” (Edgerton-Tarpley,
2005). Ultimately the famine would deal another blow to traditional Confucian values in a country already under attack from the modernizing forces of the outside world.

1931 Yangzi & Huang River Floods

“The deadliest natural disaster ever,” “the worst disaster of the 20th century,” “the greatest disaster in China’s history,” “the deadliest water-related disasters in human history” (Harnsberger, 2002): All of these labels have been attached to the massive flooding of the Yangzi and Huang rivers in central China that occurred from July to November 1931. Central to Chinese life and economy, the Yangzi and Huang rivers have also been central to the history of Chinese disasters. The Yangzi, flowing 6,300 kilometers and literally dividing China in half geographically, has been at the center of a debate about flood control since the beginning of the twentieth century.

The most controversial response to the flooding problem has been construction of the Three Gorges Dam, which began in 1994 and will be completed in 2011 with installation of the final electrical generators. The Huang River, whose length is more than 6,100 kilometers, has produced more than fifteen hundred floods in 3,500 years and is responsible for killing the most human beings in natural disasters, thus its nickname “China’s Sorrow.” At the time the 1931 floods received scant attention from the world press because they occurred within the context of a civil war raging in China between the Communists and nationalists, an invasion of Manchuria by the Japanese, and a world gripped by the Great Depression.

A confluence of weather-related incidents preceded the floods. A drought in the region, combined with heavy snows in the winter of 1930–31, severe thawing in the spring of 1931, and rains in the summer of 1931 that dropped nearly one-half of central China’s annual precipitation in one month, caused extreme rises in the rivers’ waters. More important, the region was struck by seven cyclones in July alone, a month that generally averages only two cyclones. The additional waters not only caused the main rivers to rise but also caused the nearly seven hundred tributaries to swell, setting the stage for a calamity. The flooding affected an area of 112,000 square kilometers, covering some of China’s most fertile farmland. In places the flood waters were 3–4.5 meters deep and kept the affected area flooded for three to six months. Damage estimates ranged from $1.4 billion to $2 billion (in 1931 dollars). The floods left 40 million people homeless and an estimated 400,000 to 4 million people dead. There were also unconfirmed reports of people selling their wives and daughters and practicing infanticide and cannibalism. The worst tragedy of the floods occurred on August 25, when the water in the Grand Canal collapsed the dikes around Gaoyou Lake, drowning 200,000 people.
In response to the disaster the Chinese government committed $600,000 in relief aid, while the American Red Cross offered $100,000. Emperor Hirohito of Japan personally donated $27,000 to aid survivors; two months later, on 18 September, his armed forces invaded Manchuria. The League of Nations offered the use of its epidemiologists to stem the resultant spread of diseases, while the U.S. Navy helped to reestablish communications between the city of Hankow and Shanghai. The famed U.S. aviator Charles Lindbergh assisted in relief operations. The Chinese government’s National Flood Relief Commission embarked on a rebuilding program that included constructing new dikes, levees, and retention basins, although the work took nearly twenty years to complete. After 1950 the government also undertook programs to improve the main river protection systems, including flood warning and evacuation plans as well as better controls to minimize the spread of diseases.

1976 TANGSHAN EARTHQUAKE

On 28 July 1976, coal miner Li Yulin drove an ambulance for six hours to Beijing to inform leaders of the central government that the city of Tangshan had been destroyed by an earthquake. Scattered throughout the country were five thousand earthquake-monitoring locations, installed after the 1966 Xingtai earthquake to detect seismic activity and to alert officials. However, the system failed on this day in 1976. Lasting about fifteen seconds, the earthquake struck Tangshan in the early morning when nearly all of its inhabitants were asleep. Chinese officials initially remained silent about the disaster, although the international community was aware, because of seismographic readings, that a devastating quake had occurred.

A city of 1 million people located in Hebei Province 160 kilometers southeast of Beijing, Tangshan was China’s largest producer of coal as well as a steel center manufacturing engines, trains, and heavy machinery. The Tangshan quake is believed to have been the worst earthquake in the twentieth century and the second-worst earthquake in history behind the Shaanxi quake of 1556.

The Tangshan quake registered 7.8–8.3 on the Richter scale. The calamity was described as follows: “the ground turned clockwise for a few seconds, then counterclockwise, then thrust upward” (Spignesi 2005, 48). Almost immediately 650,000 homes were destroyed, along with hospitals, train tracks, bridges, industrial plants, reservoirs, electrical lines, water pumping stations, and factories. The loss of the city’s infrastructure hampered rescue efforts. The damage was compounded the next day by an aftershock measuring 7.1. The damage occurred within a 30,000-kilometer area and was felt over one-third of the country. As it had in the Shaanxi earthquake, the quality of building construction played a major role in the Tangshan devastation. The quake intensity measured XI on the Mercali scale—another scale, with a range from I to XII, used to measure earthquake force—but the buildings were designed to withstand shocks of only VI on the scale. Nearly 85 percent of Tangshan’s buildings were located on the unstable Luanhe River’s floodplain. The ground underneath the buildings was literally liquefied by the tremors.

Death Count Disputed

Deaths were largely caused by injuries and disease. Approximately 80 percent of the deaths occurred because victims were buried under debris, unable to dig themselves out or to survive until rescued. To this day there is not an accurate total of the dead because the Chinese government refuses to release a final tally. Officials initially calculated the number of dead at 655,000 but in 1979 lowered the number to between 240,000 and 250,000. In The Great Tangshan Earthquake of 1976: An Anatomy of Disaster, the authors, officials of the State Seismological Bureau, pinpointed the number of dead at 242,919. Outside experts have disputed the government’s numbers, arguing that the total may have been closer to 750,000. Regardless, the government, after a few days’ delay, mounted a massive rescue and relief operation. China’s People’s Liberation Army (PLA) sent 150,000 troops to the area; however, the troops were improperly equipped and were forced to dig with their bare hands, thus slowing rescue operations. Nearly four hundred aircraft per day operated in and out of the quake zone, and 160 special health-care trains provided medical assistance. The government even sprayed disinfectant to stem the spread of disease.

The overall damage was estimated at $1.25 billion (10 billion yuan). Ultimately officials decided to rebuild the city on the same location at a cost of nearly $8 million. The project took nearly ten years. The rebuilt Tangshan reflected the overall design of the city and the construction...
of buildings suitable to an earthquake zone. Buildings were constructed of materials such as reinforced concrete to better withstand earthquake forces. The better building practices were incorporated into an updated seismic design code released in 1978. The updated code was designed to reduce deaths and injuries in the event of another earthquake by creating wider and safer spaces between buildings, reducing congestion to facilitate access by rescue vehicles and heavy machinery needed for rescue operations, and creating more parks and open spaces that can accommodate temporary shelters or hospitals for the displaced or injured. Guidelines for rescue and recovery operations also were updated. Planners recognized that rescue workers need appropriate equipment, that the control of the flow of traffic is essential to permit heavy equipment access to a disaster zone, and that city planning needs redundancy in the “lifelines”—for example, roads, bridges, water, and electrical supplies—to avoid the shutdown of infrastructure needed for relief and rescue operations.

**Improved Response**

New policies also called for moving the displaced population into permanent dwellings as early as possible to minimize the economic, social, and psychological effects from a quake. Lastly, the bureaucratic processes for warning local populations of an impending quake were revised. Last-minute warnings had preceded the Tangshan quake, but officials had too little time to process the information and warn citizens. For future disasters local revolutionary committees were given the authority to warn citizens directly without the delay of channeling information through China’s vast state bureaucracy.

Socially, the Tangshan quake reinforced in the minds of many Chinese the traditional notion that natural disasters foretell the death of emperors and political leaders. Occurring in late July, the earthquake preceded the death of Chinese Communist Party leader Mao Zedong by seven weeks (Mao died 9 September 1976). Politically, the quake hastened the end of the Cultural Revolution (1966–1976). The death of Premier Zhou Enlai in January 1976 and the feebleness of Mao set off a power struggle within the Chinese Communist Party. Leaders attempted to use the disaster in Tangshan to demonstrate the strength of their leadership. They refused international assistance, instead choosing to organize a “Resist the Earthquake, Rescue Ourselves” campaign to assist victims of the quake. The Gang of Four saw the disaster as an opportunity to “display the socialist system’s superiority of being self-reliant” (Xinhua News Agency, “30 years after the Tangshan Earthquake”). Jiang Qing (Madame Mao), a member of the Gang of Four, spoke on state radio not to remind the Chinese people that China’s immediate priority was Tangshan but rather to denounce Deng Xiaoping, one of the leading reformers calling for modernization. Deng would become China’s premier in the 1980s and 1990s.

Upon Mao’s death Hua Guofeng ascended to the chairmanship of the Communist Party. Hua received overwhelming public support largely because he made a personal visit to the Tangshan disaster area. Hua had the Gang of Four arrested, put on trial, and imprisoned, effectively ending the Cultural Revolution and ushering in a new era of openness and economic growth for the country.

**2008 SICHUAN EARTHQUAKE**

China’s deadliest earthquake since the 1976 Tangshan earthquake struck at 2:28 p.m. on 12 May 2008, in Sichuan Province. Nearly 15 million people lived in the quake zone, which is also home to the Wolong Nature Preserve, the largest panda bear reserve in China. The reserve was nearly 80 percent destroyed or damaged, threatening China’s national symbol. Registering 8.0 on the Richter scale, the quake was felt as far as 1,500 kilometers away in Beijing as well as in the neighboring countries of Taiwan, Vietnam, and Thailand. More than 21,000 aftershocks were reported as of June 2008, according to the China Earthquake Administration. The hardest-hit area was within 100 kilometers of the epicenter, with nearly 80 percent of structures destroyed in smaller cities and villages. Bridges collapsed, dams cracked, schools crumbled, and 3.5 million homes were destroyed. The Chinese government mobilized 130,000 soldiers, police officers, and relief workers to assist those most affected by the destruction.

The State Council of Information reported that as of early July 2008 the toll stood at 69,195 dead, 374,176 wounded, and 18,389 missing. The number of people evacuated from the quake zone reached 1.5 million, but 14 million survivors needed to rebuild their homes.
Transparent and Personal

As has been the case after previous disasters, Chinese society underwent political and social transformations after the Sichuan earthquake. The official response to the disaster was more transparent and personal than responses of the past. Media coverage of the quake was immediate, ongoing, and open. The state news agency, Xinhua, not only broke the story but also regularly updated the casualty figures and news on rescue and relief operations. The news agency also provided the first-ever announcement of the number of estimated dead. Chinese Central Television initiated live, nonstop coverage—an unprecedented action for a natural disaster in China. Home videos, cell phone pictures, and personal commentary flowed unrestricted onto websites. The State Central Propaganda Department initially ordered that journalists could not enter the quake zone; however, two Chinese journalists from The Oriental Morning Post, Yu Song and Wang Jialang, ignored the order and filed the first unofficial accounts of the quake along with images. Their actions forced the propaganda department to rescind its order.

In another surprising action, albeit on a more personal note, Prime Minister Wen Jiabao, China’s leading political figure, flew immediately to the earthquake zone to direct rescue and relief operations. “Grandpa Wen” declared a “people first” policy in stark contrast to official response to the 1976 Tangshan earthquake, when Communist Party officials first denied the quake, then attempted to cover up its severity, instead focusing the Chinese people’s attention on denouncing Deng Xiaoping, one of the leading reformers calling for modernization. However, Wen’s action is not unprecedented: Prime Minister Hua Guofeng had made a personal appearance at the site of the 1976 Tangshan quake.

Police set up roadblocks outside the Sichuan zone to facilitate the donation of cash and other gifts for the survivors as well as to monitor the flow of “volunteers (upwards of 10 million people) from as far away as Beijing, Shanghai and Hangzhou” (Xinhua News Agency, “From Tangshan to Wenchuan”) who streamed into the disaster area. Foreign and domestic donations to aid quake victims surpassed $6.4 billion. The government established the biggest charity fund ever to handle the stream of donations. Xinhua reported that “the Industrial and Commercial Bank of China (ICBC) announced ... that it has provided 8.06 billion yuan (1.17 billion U.S. dollars) in loans to companies and public utilities for reconstruction ... The ICBC, the country’s largest lender, also said it had signed a financing agreement for supporting reconstruction projects with the municipal government of Chengdu,
the capital of Sichuan Province. China’s financial agencies had issued a total of 52.95 billion yuan in reconstruction loans for quake-stricken areas by Sunday, of which 44.6 billion yuan went to the hardest-hit Sichuan. Meanwhile, the government allocated 54.82 billion yuan to a disaster relief fund, including 49.71 billion yuan from the central budget and the rest from local budgets” (Xinhua News Agency, “ICBC provides . . .”).

In another first, the nation’s blood banks filled to capacity, and additional donors were instructed to wait before donating.

**Foreign Rescuers Admitted**

In addition to cash donations, the Chinese government accepted rescue teams from Japan, Taiwan, and South Korea, thus reaping the additional consequence of improved relations between the donor countries and Beijing.

In response to the disaster the Ministry of Education and the Ministry of Housing and Urban-Rural Development released new standards for school construction. The government also imposed price controls on food and transportation within the quake zone to prevent profiteering. The government also agreed to pay the medical expenses of those injured or affected by the quake. Communist Party officials organized mental-health case workers in a first-ever attempt to provide mental and psychological services to victims of a disaster. The government also ordered that flags be flown at half-staff throughout the country to honor the victims of the quake—the first time that ordinary people have been honored in this fashion. A period of national mourning was declared from 19–21 May, and all public events, including the 2008 Olympic Games torch relay, were suspended.

The most closely followed story resulting from the quake’s destruction was the fallout after ten thousand schoolchildren were killed when more than seven thousand schools collapsed. The deaths of so many children led to public protests against faulty school building construction, negligence, and allegations of corruption. (Since 2001 the Chinese government has allocated more than $1.5 billion to repair and upgrade schools; however, school construction codes are rarely enforced.) The Chinese government launched an investigation into the charges but attempted to keep the investigation low profile. The government, aware that rural schools are highly susceptible to damage from quakes, asked Chinese news organizations to discontinue their reporting on unsafe schools. The unusual public demonstrations by parent-protesters resulted in violent clashes with police and arrests. In response to protests by parents who lost their children when schools collapsed, the government issued checks for $144 to parents whose children were killed. This payment is the usual subsidy provided under China’s “one-child policy,” a subsidy distributed when parents reach age sixty. The government promised additional monies when the government investigation establishes additional human negligence regarding school construction. The government also agreed to provide compensation for any children injured in the quake. These monies are crucial because without children Chinese parents, lacking an old-age safety net, face potentially heavy burdens of care in their old age. China has been forced to suspend its “one-child policy,” a policy begun in the late 1970s to address China’s population explosion. The government updated the policy to exempt families with children who were killed or injured by the earthquake, and that these families would need only to obtain a certificate permitting them to have another child. Furthermore, families who lost a child in the quake are now permitted to adopt, without limitations, any of the four thousand estimated orphans whose parents were killed in the quake. The adoption of quake orphans will not affect any future births under the one-child policy, which is still in place for families not affected by the quake.

**Man-Made Disasters**

**1975 Banqiao Dam Collapse**

Rain began falling in Henan Province on 5 August 1975, the result of a typhoon that had swept in from the South China Sea. In the next three days 1,060 millimeters of rain fell. At 1 a.m. on 8 August the Banqiao Dam, located on the Ru He River, collapsed, caused in large part by the lack of excess capacity in the reservoirs of the Huai River basin to handle the additional water. Seven hundred million cubic meters of water were released, creating a wall of water 6 meters high and 12 kilometers wide, sweeping away entire villages such as the Daowencheng commune, where 9,600 people were killed. Banqiao’s sister dam, the Shimantan on the Hong He River, had collapsed a half

© 2009 by Berkshire Publishing Group LLC
hour earlier, its reservoir emptied of 120 million cubic meters of water in five hours. Creating a domino effect, these twin walls of water caused sixty-two other dams downstream to fail. The worst dam disaster in human history had begun.

Built in the 1950s after an episode of severe floods, the Banqiao Dam was designed to control flooding in the Huai River basin. "Harness the Huai River" became the official motto for the building program, which was intended not only to control the river and flooding but also to create a reservoir for irrigation and electrical generation. The dam was built where colliding weather systems from north-central Asia and the South China Sea meet. Along with the Shimantan Dam and a series of smaller dams, the Banqiao Dam was designed to withstand a flood the volume of which might occur once every one thousand years. The dam project would serve as the model for the Great Leap Forward campaign to create a large-scale water conservancy program, one whose primary priority was water accumulation and irrigation and whose secondary priority was drainage and flood control. Unfortunately for residents of the Huai River basin, the typhoon that swept into the area was of a magnitude expected to be experienced once every two thousand years. However, despite the confluence of remarkable weather events, the collapse of the Banqiao Dam was attributable largely to human error.

Rainfall Underestimated

The first human error occurred in rainfall prediction. Accurate rainfall prediction by Chinese meteorologists was limited by their lack of scientific knowledge. In early August the Central Meteorological Observatory in Beijing had forecast 100 millimeters of rain. In fact, the rainfall total was 1,060 millimeters. The water levels in reservoirs in the Huai River basin had been kept too high, thus providing little excess capacity to contain the greater rainfall. However, despite the confluence of remarkable weather events, the collapse of the Banqiao Dam was attributable largely to human error.

Experts have concluded that the design of the dam—built (and repaired) with Soviet assistance—was to blame for its collapse. The dam’s construction did not include crucial flood-control devices, such as diversion channels and dikes. During its initial construction cracks in the dam and spillways had appeared, forcing engineers to make repairs. Chinese officials believed that the repairs had allowed for the construction of what they termed an “iron dam”: a dam that would not collapse regardless of the situation. Furthermore, the construction of the dam was hurried in order to meet official target dates. However, one of China’s senior hydrologists and dam designers, Chen Xing, warned officials of dangers to the dam. Most important, in the original design the Banqiao Dam was to include twelve sluice gates (artificial channels that allow control of the flow of water). However, a local Chinese official overruled Chen, declaring him to be “too conservative,” and lowered the number of sluice gates to five. Ultimately, Chen would be removed from the project because of his constant criticism. As the water levels behind the dam began to rise during 5–7 August, the sluice gates were opened to relieve the pressure of the additional water, but all five were partially blocked by silt and sediment buildup. The rapidly rising water levels, compounded by the inadequate functioning of the spillways, caused the level of the reservoir to exceed the capacity, or height, of the dam, resulting in a condition referred to by dam experts as “overtopping.” The results of this phenomenon are twofold: Either the structural integrity of the dam becomes compromised, or the land on either side of the dam erodes, effectively separating the dam from its earthen anchors. In the case of the Banqiao Dam collapse, the former result occurred. As the millions of cubic feet of water crashed through the dam, one of the dam workers, part of a gang of workers engaged in a futile effort to prevent the dam’s collapse, exclaimed that “the River Dragon has come!” (Qing 1998, 33).

No Warning System

The structural failure of the dam was compounded by the lack of an early warning system and comprehensive evacuation plans. One of the immediate results of the dam’s collapse was the failure of the region’s communication and transportation networks. That failure contributed to the loss of life and the inability of the relief workers, especially troops of the People’s Liberation Army, to reach survivors for nearly two weeks. The floods from the collapse of both dams and the supporting series of dams affected twenty-nine counties and municipalities. The floodwaters spread over 1 million hectares of farmland, causing more than 1 billion yuan ($525,600,000) in damage. A week after the
initial disaster several smaller dams in Henan Province were dynamited to allow the floodwaters to escape farther downriver. The dead resulting from the immediate floods totaled 26,000, while an additional 145,000 died from resultant disease and famine. In all, 11–12 million people were affected by the floods. Six million buildings were destroyed. The absolute numbers may someday be revised after a more careful study of the official documents, according to Wang Yaurong, then an official with the Henan Province Department of Water Resources. The Chinese government suppressed all news of the disaster, in line with a longstanding policy not to publicize disasters because they fall under the category of state secrets. Not even external news agencies reported on the disaster; not until February 1995 did the world learn of the disaster in the Huai River basin when Human Rights Watch published news of the Banqiao Dam collapse in a report on the Three Gorges Dam project on the Yangzi River in Hubei Province.

Exactly what Chinese officials, engineers, and dam designers learned from the Banqiao Dam collapse is difficult to tell. Clearly there was the need for some form of early warning system with safer communication networks and a level of redundancy built into the system in the event of a catastrophic collapse. An academician, Li Zechuan, recommended that a database containing “meteorological, hydrological, environmental protection, forestry and agricultural departments be established to form a uniform environment monitoring network” (People’s Daily Online, 2005). An examination of the design, construction, and support systems of the Three Gorges Dam might offer clues to what was learned from the collapse of the dams. Not to be deterred by the dams’ failures, by 1993 China had rebuilt many of them, including the Banqiao.

2005 JILIN CHEMICAL PLANT EXPLOSION

Nearly 300 million of China’s 1.3 billion people do not have access to clean water. Approximately 70 percent of Chinese waterways are contaminated, and 90 percent of urban water supplies are severely polluted. The safety of water supplies is even more comprised by pollution from China’s factories, especially in the chemical industry. Accidents in the chemical industry were brought into sharp focus in 2005 when an explosion occurred at the Jilin chemical plant.

On 13 November 2005, a blockage formed in a processing tower used in the manufacture of benzene at the Jilin Petrochemical Company, a subsidiary of the government-owned China National Petroleum Corporation in northeastern Jilin Province. An explosion followed, accompanied by a series of smaller explosions, and a cloud of smoke appeared over the plant. Storage tanks erupted, spilling 90 metric tons of toxic chemicals into the Songhua River. The chemicals released were primarily benzene, phenylamine, nitrobenzene, and aniline, which are used in the manufacture of plastics, detergents, pesticides, shoe and floor polishes, and paint solvents. If humans are exposed to them at unsafe levels, dizziness, drowsiness, unconsciousness, and even death can result.

The spill affected not only Chinese citizens living along the Songhua but also millions of others living along the connecting rivers, especially Russians living along the Amur River, which empties into the Sea of Okhotsk. Most immediately in danger were the residents of Harbin, China’s eighth-largest city with 3.5 million residents. Harbin is located 350 kilometers downstream from the Jilin plant and draws nearly 90 percent of its drinking water from the Songhua River. According to the Russian Far East Emergency Department, the spill endangered seventy population centers—a total of 1 million people—along the Amur. According to the United Nations Environment Programme (UNEP), which investigated the accident, the Jilin spill was “probably one of the largest transboundary chemical spill incidents in a river system in recent years” (United Nations Environment Programme 2006, 16).

Plant managers and local political officials initially attempted to keep the spill a secret. As they attempted to dilute the spill by releasing additional waters from a local reservoir, they waited for five days before informing officials in the neighboring province of Heilongjiang and the central government in Beijing. An anonymous source in the Jilin provincial government leaked word of the spill to the China Business News. Eight days passed before Harbin city officials received notification and shut down the city’s water supply, explaining to residents that the pipes were undergoing maintenance. Ultimately, after they had been told that a toxic spill had polluted the river, Harbin officials informed city residents that the water supply would be unavailable for four days; this represented the largest shutdown of a municipal water
supply in recent Chinese history. Chinese Communist Party officials organized water trucks, decorated with banners reading “Love the people—deliver water,” to provide potable water to city residents while soldiers began to dig new wells.

**Notification Delayed Again**

Eleven days after the spill the State Environmental Protection Agency (SEPA) finally notified Russian officials of the spill and of the threat posed to 600,000 Russian citizens living in Khabarovsk, which also depends on the Songhua River for drinking water, as well as the exposure to residents living along the Amur River. Tensions between the two nations rose. The mishandling and denials by business and political officials at all levels highlighted a long-standing practice of placing industry concerns above that of public health. The UNEP report on the accident criticized the Chinese government for its failure to communicate appropriate information to the public, which delayed an adequate response to the catastrophe.

The fallout was swift. Xie Zhenhua, head of SEPA, resigned 2 December 2005. His resignation marked the first time a high-ranking Chinese official was forced out of office because of an environmental disaster. Yu Li, general manager of the Jilin Petrochemical Company, was dismissed on 4 December. Wang Wei, deputy mayor of Jilin who denied that the accident had caused any environmental damage, committed suicide by hanging on 7 December. The Chinese government issued a formal apology to the Russian Federation for the accident. Six people died, and nearly seventy were injured in the immediate aftermath of the explosion.

However, a number of positive developments resulted from the Jilin accident. China and Russia established a joint monitoring program to assess the long-term repercussions from the spill. SEPA invited a team of investigators from UNEP to tour the affected areas, meet with local and national officials to discuss measures taken to address the spill and protect public health, and, according to the final UNEP report, “provide possible advice to the government of China on the environmental disaster prevention in the future” (United Nations Environment Programme 2006, 4). The report assessed the spill and the local response while providing a number of recommendations including: environmental impact studies on water, soil, and air contamination of the affected areas; a comprehensive investigation to determine causes of the spill and assess ways to prevent future disasters; a recommendation that China and Russia provide independent access to the river spill for testing; regular monitoring of water quality; upgraded policy and enforcement of regulations; and acceptance of an offer of continued support from UNEP. Missing from the UNEP report were measures to deal with public health because SEPA objected to including a public health expert on the investigation team. However, SEPA initiated unprecedented actions to investigate businesses, government officials, and individuals responsible for the spill.

**Sanctions Threatened**

In addition, the National Bureau of Production Safety Supervision Administration threatened all chemical plants and state-owned companies with stiff fines for environmental violations. Additionally, any officials who do not cooperate with investigations or are found to have covered up accidents will face severe punishments. China committed to spending $3.3 billion to clean up the spill as well as additional sums to upgrade municipal and wastewater treatment plants to improve water quality. Beijing also issued a directive to local officials to create emergency plans for future environmental incidents. The directive also ordered factories to improve environmental safety standards, stepped up government monitoring of environmental safety at factories along rivers, and required that all new chemical plants be built inland far from waterways and that existing plants near waterways construct holding ponds for contaminated water. Zhou Shengxian, director of SEPA, in a report to the National People’s Congress urged China to improve environmental safety or face catastrophes similar to Jilin. Zhou said China’s astounding economic growth in recent years has polluted the country’s air, water, and soil. His comments focused on the chemical industry because one-half of the 21,000 chemical plants in China are located along the Yangzi River and Huang River, which provide drinking water to millions of Chinese.

However, the new regulations have some flaws. The fines for noncompliance with environmental regulations are so low that offenders are not deterred from engaging in harmful activities (Jilin Petrochemical Company received the maximum fine of $125,000 for the 2005 spill). Local officials are responsible for issuing permits, but
their performance evaluations are still largely based on economic output, so local officials are more likely to keep plants running even if those plants are environmentally suspect. Multinational corporations in China are hiring the better environmental officials away from local companies. Encouragingly, government testing in spring 2006 indicated that water in the Songhua and Heilongjiang rivers had returned to normal levels, although the Russians indicated higher-than-normal levels of chemicals in the Amur River because the spring thaw washed contaminated water into the river. Nevertheless, Worldwatch Institute, an international independent research organization focusing on sustainability issues, concluded that since early 2006 the Chinese central government “shifted its rhetoric from a focus on economic growth at all costs to stressing a ‘harmonious society’ where considerations of development and environment coexist” (Mastney et al., 2006). The Chinese government is engaging in more than mere rhetoric. In a survey conducted in 2006 SEPA investigated 7,555 chemical plants for environmental risk; 45 percent were found to be sources of pollution, while 3,745 plants were ordered to adopt stricter pollution controls, and 49 plants were ordered to move. The problems that confront China in terms of development and environmental safety lie not in the realm of regulations (China has some of the best environmental laws in the world) but instead lie in lax enforcement and outdated plants in the chemical industry. However, Chinese companies, along with government officials, are working to improve plant safety and adherence to environmental standards.

Conclusion

Disasters have been a recurring phenomenon throughout Chinese history. All Chinese, both officials and citizens, have usually mobilized to respond to the crises. The various responses, first established in the classical period, have been based on historical precedents. State responses appear never to have been the same, nor have the consequences of those actions been similar. Regardless of the form or type of disaster, the consequences have usually been accompanied by social and political change. Despite attempts by the Chinese government to keep disasters secret, the outside world has become increasingly aware of China’s disasters and ready to respond and provide assistance. In the contemporary age, the scale of disasters and the inability of the Chinese to keep such disasters from being publicized has caused the Chinese government to be more accepting of foreign aid and relief assistance. The Chinese have also reformed and upgraded their technological know-how to better meet the challenges posed by the reality of continuing catastrophes.

### Natural Disasters and the Mandate of Heaven

In ancient Chinese beliefs, natural disasters were seen as a warning from Heaven that the reign of a ruler was on the verge of collapse. An emperor’s ability to rule was said to reflect the cosmic sanction bestowed on his reign by tianming, or the “mandate of heaven,” which Chinese believed was signified by peace and harmony within his realm. Traditional political philosophers held that moral legitimacy was a vital component of tianming and that if the moral bonds between ruler and ruled were irrevocably violated, the all-embracing forces of “heaven” from which an emperor drew his “mandate” to rule as “the son of heaven” would be withheld and his dynasty would collapse. Before such a fall, it was believed that “heaven” would signal its displeasure with such portents as natural disasters and popular rebellions. “We are informed that when heaven gave life to the human race it instituted rulers to look after its members and to keep them in order,” explains the Han-shu, a first-century history of the former Han Dynasty. “When a ruler of mankind is not possessed of appropriate qualities, or when his administrative measures are not fair, heaven points out these failings by means of calamity so as to give warning of disorders.”

---

Since prehistoric times Chinese have tried to predict the future by interpreting oracle bones, signs in the sky, and stalks of plants. The newest form of divination practiced in China is feng shui.

Divination (practices that seek to predict the future) seems to have been common everywhere among human societies since prehistoric times. Primitive hunters presumably used some form of divination to determine which animals to hunt and when, whereas agricultural communities relied on divination to decide when and what to plant. Within recorded history divination has long been important in both China and the Western world.

Chinese practices of divination can be traced back to the oracle bones of the Shang dynasty (1766–1045 BCE). Animal shoulder blades and, later, turtles’ lower shells (plastrons) were inscribed and heated until they showed cracks, which were then interpreted by a diviner or Shang king. Surviving fragments indicate a belief in a but not personified powers, some identified with forces in nature, such as “the Huang (Yellow) River,” others representing honored ancestors established as spirits.

Collectively, these powers are associated with a celestial force called Tian 天. They were seen to possess power to control all things, as manifested in natural phenomena. Rulers depended on observations of signs in the sky in order to infer the will of Tian. As a result, Chinese astronomical observations were extraordinarily accurate from an early
time, starting in the Shang dynasty, notably recording an
eclipse in 1302 BCE that modern scientists have confirmed.
Around that time the Chinese diviners began dividing the
sky into twenty-eight segments or lunar mansions.

By the time of the Zhou dynasty (1045–256 BCE) ap-
peals to Tian seemed increasingly impersonal, perhaps
in part because the Zhou usurpers were not likely to look
for favor from the Shang ancestors they had defeated.
Turtle-shell divinations declined because of the use
of new techniques, most notably the divination of stalks of
the yarrow or milfoil plant. This divination yielded six-
line hexagrams to be interpreted via the text Zhouyi 周
易, which in its earliest form seems to have been in use
before 801 BCE. In all these circumstances humans had to
interpret the results.

As of about two thousand years ago, the I Ching 易经,
the outgrowth of the Zhouyi, clarifies the enduring pre-
sumptions on which the traditional Chinese worldview
is based. This text presumes that things are not regular
and predictable but always open to change, a vision of
existence basic to Chinese civilization. As this world-
view posits a world of endlessly shifting forces, it encour-
ages humans to focus very much the strategy and tactics
needed to position themselves fruitfully in such a world.

Divination through the I Ching focuses on two aspects
of a situation: how it is to be interpreted and how it is to
be negotiated. Interpretation is important because things
are never deemed to be perfectly clear; thus the Chinese
tolerate a certain degree of ambiguity in the way they con-
strue any given reading of a situation. Furthermore, divina-
tion through the I Ching not only assumes that everything
changes, but also that everything is connected, so that when
one factor changes, other, related things will also change.

Compared with traditional techniques of divination,
modern science approaches the study of the future by
trusting that what caused events in the past will continue
to do so in the future. Therefore, science interprets events
in a search for general rules that will always apply because
they are presumed to be universal natural laws. The I Ching
classical text follows an opposite expectation. It presumes
that the determining forces in the world are not regular
and predictable but rather are always open to change, a
vision of existence basic to Chinese civilization.

The third and newest form of divination to be prac-
ticed in China is feng shui 风水. This form inspects the
landscape and its prominent features (orientation in
relation to heights of land, water, magnetic fields, points
of the compass) in order to discern places and positions
favorable for human implantations (cities, buildings,
tombs). Traces of such practices are found as early as the
Han dynasty (206 BCE–220 CE), but they became estab-
lished during the Song dynasty (960–1279), when mag-
netic compasses emerged as functional instruments. In
feng shui the diviner sets out to determine emplacements
favorable for the movement of vital energy (qi moves most
naturally along winding paths) and to protect against de-
structive forces (sha, 影, is at its worst when moving along
straight lines). In recent centuries diviners have produced
elaborate compasses that bring together many kinds of
Chinese cycles (yin/yang, 5 phases, 8 trigrams, 12 zodiac
animals, 28 lunar mansions, 64 hexagrams, and so on).
The function of these different divinatory contexts was to help read the current cyclical situation of any particular place in Chinese space.

Although feng shui was publicly discouraged in the middle of the twentieth century, it has not disappeared, finding new acceptance in Western society as well as flourishing in Singapore and elsewhere Chinese have emigrated. Now, there are signs of a revival of interest in feng shui in the People’s Republic of China.

Another form of divination that traces its roots back to ancient China is less formal, but perhaps more widespread than any of the others mentioned above. The phenomenon of “luck-language” is a linguistic feature of Chinese and is based on a survival of classical Chinese isomorphism concerning the relation of words to the world. In that relationship, words are seen as activating energies that may influence what actually happens in the world. This effect is launched through similarities in sound. In Chinese, there are many words that sound alike but have different meanings (homophones). For example, the number 4 四 is pronounced sì, with a pronunciation that varies only in tone from the word for death (sǐ, 死), therefore relating, at least orally, the number 4 to death. In such a worldview, any unnecessary evocation of the word for death, even if only in the mind’s ear, may seem to increase the likelihood of death-related events. Hence it would be prudent to avoid these words whenever possible.

The same implication holds on the positive side of luck-language: the fish as a traditional motif in New Year celebrations depends on the identical pronunciation of fish (yu, 魚) and surplus (yu, 余). If there is even a slight chance that associating one’s festivities with fish will encourage prosperity in the new year, why not?

All these Chinese word-world associations can be understood in a very different way as implicit expressions of respect for the fact that there are limits to what humans can control in a world that is defined in terms of larger, invisible forces shaping what happens to and around them. Indeed such a worldview is central to the I Ching and may be said to constitute a fundamental presumption of Chinese divination tradition in general.

DONG Qichang

Dǒng Qíchāng 董其昌

1555–1636  Ming dynasty painter, art critic, and official

Dong Qichang, born in Huating (present-day Songjiang, Shanghai), was a distinguished Ming painter, calligrapher, art critic, and official whose landscape paintings were noted for their simplicity and elegance. Both his art theory and his practice would have a lasting impact on the development of Chinese art.

Dong Qichang studied from 1570 to 1580 with a circle of scholar-officials, artists, and collectors in and around his hometown of Huating (now Songjiang, Shanghai). In 1589 Dong placed second in the national huishi (metropolitan exam). Subsequently he was appointed as a bachelor of the imperial Hanlin Academy, a membership that was virtually a prerequisite for those ambitious scholars, including Dong, to rise to high political positions. Eventually Dong was promoted to be the court libushangshu (director of the Department of Rituals). He also briefly tutored the crown prince of the Ming emperor Wanli (reigned 1573–1620).

Dong's acquaintanceship with other high scholar-officials helped him gain access to fine collections of ancient Chinese art, particularly landscape paintings of the Five Dynasties period (907–960 CE). Dong, painting with ink on a paper scroll, gradually developed his own style, alternating a dry brush for shading and rubbing to contrast the effects of a wet brush. Dong's favorite subject was landscape. He painted scenes that were not true to life but rather showed deliberate dissonances in the relationship between foreground, middle ground, and background; he effectively flattened space so that mountains, trees, and rocks functioned less as representational forms than as semi-abstractions. Using fresh, moist ink he accentuated the diagonal lines of a composition to evoke the varied texture of rocks and mountains. Although Dong would occasionally include a hut or studio in his paintings, he avoided human figures.

Dong's overall painting style could be divided into earlier and later paintings. The early paintings often contained monumental mountains that rose almost to the top of the scroll. The meandering ridges of the central mountains directed the viewer's eyes upward toward the apex. An emphasis on gaoyuan (high extension) was obvious. Dong's later paintings, by comparison, reduced the contrast of height between the central mountain in the background and the lower mountain in the foreground. The broadness of the solid mountains suggested the vastness of nature. Led by Dong Qichang, the circle around him was later called the “Huating school of painting.”

Dong was also accomplished in calligraphy, long considered the highest form of artistic expression in China. He excelled in cursive and running scripts. His calligraphy synthesized styles of the Tang (618–907 CE), Song (960–1279), Jurchen Jin (1125–1234), and Yuan (1279–1368) dynasties but was unique in its simplicity, elegance, and straightforwardness. Dong introduced certain terms that had evolved to discuss the expressive properties of brushstroke and composition in calligraphy into the criticism of painting, such as opening and closing, rising and falling, and the balance between solid and void.

Dong preferred learning from the ancient masters to copying from nature. He argued that the literati painting
(a style that melded poetry and calligraphy with painting) satisfied "scholarly taste." In his view literati painting expressed the painter’s personality. Focusing on the mind rather than on the skill (and echoing Ming philosophy—which held that the mind, not the physical world, is the basis of reality), literati painting paralleled the spontaneity of the Southern Chan Buddhist school. Dong downplayed often decorative court painting, with its emphasis on technical skill, which according to him fell into the category of "sweet vulgarity." This twofold division correlated with the Chan Buddhist distinction of the Northern and Southern schools (conservative and progressive, respectively; their classifications had nothing to do with geography).

Dong Qichang’s artistic theory and practice had a lasting impact on the development of Chinese painting and calligraphy until modern times.

DONG Zhongshu
Dǒng Zhòngshū 董仲舒

C. 195–105 BCE  Han dynasty philosopher and statesman

Dong Zhongshu 董仲舒 was the most influential exponent of Confucian thought during the Han 漢 dynasty (206 BCE–220 CE). For almost two millennia, Confucianism was sustained by the textual canon, educational institutions, and spiritual ethos developed by Dong and elaborated upon by his successors.

Dong Zhongshu was the most influential force in proliferating Confucian thought during the Han dynasty (206 BCE–220 CE) and beyond. He created a religious rationale for the authority and structure of the then new imperial Chinese state, thus renewing a tradition of theological justification for dynastic power begun when the Zhou conquered the Shang in the eleventh century BCE. For almost two millennia, Confucianism was sustained by the textual canon, educational institutions, and spiritual ethos developed by Dong and elaborated upon by his successors. Without Confucius (551–479 BCE) there would be no Confucianism; but without Dong there would be no Confucianism as it has been known for the past two thousand years.

Ill-Fated Times
Dong was born in what is now Hengshui in modern Hebei Province, a region previously known as the kingdoms of Yan and Zhao. Before the unification of China by the Qin dynasty (221–206 BCE), Yan, Zhao, and other warring states were embroiled in a prolonged struggle for mastery of the empire lost by the Western Zhou dynasty (1045–771 BCE) to “barbarian” invasions. During this time “one hundred schools” (baijia) of thought proliferated, laying the foundation for every major philosophical and religious tradition in China except Buddhism. While baijia thinkers disagreed intensely on nearly everything, they were in agreement on two points: that the lost empire of the Zhou must be reunified under a single regime and that intellectual and spiritual pluralism was a sign of living in ill-fated times. Ironically, it was the profound cultural ferment of this era that later facilitated the emergence of a new imperial order as well as Dong’s accompanying intellectual synthesis.

Classical Scholarship
Later writers credit Dong with phenomenal dedication to learning, citing the example of his having shut his windows for three years to study indoors without distraction. Dong was an assiduous student who absorbed both Confucian and non-Confucian influences.

These included the yinyang school, which claimed that all cosmic processes were deeply interconnected and could be understood in terms of the interplay between dynamic forces of yin (characterized as dark, female, moist, and receptive) and yang (characterized as lucid, male, arid, and active) at all levels of being. Other theories presented a similar cosmology but argued for the interaction of five agents, or elements or phases (wuxing)—fire, water, earth, wood, and metal—as determinative of cosmic
processes. Such correlative cosmologies implied that the smallest of human actions could affect cosmic processes and vice versa. Many baijia thinkers used such cosmologies to appeal to rulers, who, they argued, could exploit cosmic forces for the benefit of the state. At the time most Confucians eschewed such thought.

Like his forerunners at the Han court, Lu Jia (?–170 BCE) and Jia Yi (201–168? BCE), Dong won favor with the Han regime not for his Confucian convictions but by writing scathing critiques of the preceding Qin dynasty. At that time Confucianism never had received state support and, in fact, was viewed with suspicion. Like their Qin predecessors, the early Han rulers favored a combination of political philosophy and mystical spirituality known as Huang-Lao (a name taken from Huangdi, the mythical Yellow Emperor, and Laozi 老子, the legendary sage) and thus repressed Confucianism. Nonetheless, during the reign of the sixth Han emperor, Jingdi (reigned 156–141 BCE), Dong received official preferment. Jingdi was enamored of the so-called Daoist text known as the Laozi and thus resistant to Dong’s Confucian agenda. At one point Dong’s writings were interpreted by Jingdi as seditious, and he was imprisoned and sentenced to death but pardoned and released soon afterward.

**Revival of Confucianism**

Dong found his patron in Jingdi’s successor, Emperor Wudi (reigned 140–87 BCE). Wudi’s predecessors had faced challenges to their power from various rebel movements, and their own dynasty won power by rebelling against the Qin regime. At the same time, Confucians and other baijia thinkers argued that Heaven (Tian) not only brought down the Qin but also elevated previous regimes (particularly that of the Western Zhou) to power. Young, insecure, and new to the throne, Wudi was eager to demonstrate not only that Tian had given its mandate (ming) to the Han but also that Tian’s blessing still guided the dynasty.

Dong responded to this politicoreligious challenge by turning to a text, supposedly authored by Confucius, known as the Chunqiu (Spring and Autumn Annals), which purports to chronicle events in Confucius’s home state of Lu between 722 and 481 BCE. In the Chunqiu Dong discerned Tian working hand in hand with various human actors (typically virtuous rulers, moral ministers, and other Confucian exemplars) to keep the cosmos in balance by harmonizing its constitutive powers and processes (yinyang, wuxing). In effect, Dong reread pre-Han chronicles through a cosmological lens, such that heavenly norms could be seen interacting with human history, with crucial lessons for his own time. When one reads...
Dong’s description of the ideal ruler, it is not difficult to understand why Dong’s interpretation won imperial support: “As for the one who appropriates the mean of Tian, Earth, and humankind and takes this as the thread that joins and connects them, if it is not one who acts as a king, then who can be equal to this task?”

Dong’s arguments persuaded Wudi to terminate imperial sponsorship of non-Confucian traditions and appoint Dong to various high offices. Between the 130s and 120s BCE, Dong was able to recommend several pro-Confucian policies, which Wudi promptly implemented: the canonization of ancient texts favored by Confucians as the Five Classics (wujing), the state subsidy of Confucian scholarship, and the establishment of a Grand Academy (taixue) dedicated to the training of Confucian bureaucrats for service in the imperial government. By the end of the first century BCE, approximately three thousand students were enrolled in the academy, and the number exceeded thirty thousand by the end of the dynasty. Both the first-century CE Qian Hanshu (History of the Former Han Dynasty) and the third-to-sixth centuries CE compilation Chunqiu Fanlu (Luxuriant Gems of the Spring and Autumn Annals) preserve some of Dong’s most important writings.

Dong’s Surviving Vision

In 1330 a tablet displaying Dong’s name was installed in state-sponsored Confucian temples alongside the tablets of other Confucian exemplars. Texts and tablets both serve to underscore the monumental significance of Dong within Chinese cultural history. His vision of harmony between cosmos, morality, and government lives on today in contemporary Chinese political discourse.

Having had many names in history, Duanwujie 端午节, known as the Dragon Boat Festival in the West, is celebrated by racing in boats shaped like dragons and by eating a special dumpling called zongzi. The festival is now popular in many countries in Asia and in Chinese communities elsewhere; dragon boat racing has become a favorite sport around the world.

What Westerners know as the Dragon Boat Festival is one of the most important traditional Chinese festivals. The date of the festival is determined by the Chinese lunar calendar and falls on the fifth day of the fifth lunar month. On 18 December 2007, the Chinese government made the festival an official three-day holiday with paid leave.

Custom

The festival has had more than two dozen names throughout history, including Duanyangjie (First Yang Festival), Wurijie (Festival of the Fifth Day), Aijie (Festival of Wormwood), Chongwu (Double Five), Wuri (The Fifth Day), Xiajie (Summer Festival), Duanwu (Fifth of the Month), and Wuyuejie (Festival of the Fifth Moon). Only two names are used today, Duanwujie and Wuyuejie, the former being literal and the latter colloquial.

The celebration of Duanwujie involves a number of activities, varying from region to region, the most prevalent of which is racing colorful boats shaped like dragons. Others include making and eating zongzi (a glutinous rice dumpling wrapped in bamboo or reed leaves) and contests that involve standing eggs on their ends on the ground. In addition, to ward off disease, people decorate their houses with aromatic herbs like sweet flag and wormwood leaves, drink realgar wine (a reddish-orange ore of arsenic common in traditional Chinese medicine), take a walk in the country, wear scented sachets, and put up exercising signs inside and outside their houses. In the region where the provinces of Hunan, Hubei, and Jiangxi meet, there is a tradition of parading land dragon boats from village to village. The villagers believe that the boats are capable of expelling plagues. Eating zongzi and racing dragon boats have become the most popular activities throughout the Chinese-speaking world, and the egg-standing contest has turned into a popular game for children.

Zongzi is a dumpling whose glutinous rice stuffing can be sweet (usually with jujubes or red bean paste, favored in North China) or salty (with preserved ham or braised pork, well-liked in the south). A zongzi was initially contained in a bamboo tube but is now wrapped in leaves of bamboo, reed, lotus, or banana. Varieties of zongzi, with different stuffings and shapes, are found in supermarkets throughout the country.

Dragon boat racing is the centerpiece of the Duanwujie Festival and is held as a large community event. Different villages send their teams to compete. When the signal to start is given, each team paddles its individually designed dragon boat as hard as it can while its leader rhythmically
beats a drum to coordinate the paddling. Wave after wave of cheers from onlookers on the bank adds to the excitement. In 1980 China listed dragon boat racing as an official national sport.

**Origin**

The name *Duanwu* was first documented sometime in the third century, but the origin of the festival is unknown. There are at least five theories: to commemorate Wu Zixu, (526–484 BCE) a senior official of the state of Wu during the Spring and Autumn period (770–476 BCE); to commemorate Qu Yuan, (340–278 BCE) a poet and statesman of the Chu state in the Warring States period (475–221 BCE); to celebrate the Chinese dragon; to fend off plagues; and to observe the summer solstice.

Wu Zixu constantly admonished the King of Wu for neglecting the danger presented by his long-time rival, the King of Yue. The wrathful King of Wu forced Wu Zixu to commit suicide and had his body thrown into a river. According to a legend mostly circulating in Suzhou, people raced their boats to where the body fell and tried to save it from the mouths of fish by throwing *zongzi* dumplings into the water.

Qu Yuan was a poet and statesman who, like Wu Zixu, foresaw the danger of his state being overrun, this time by the state of Qin, and never hesitated to warn the King of Chu against the imminent peril. He, too, incurred the wrath of his king, who banished him from the court. In despair Qu Yuan threw himself into the Miluo River. As told by popular legend in what are today the provinces of Jiangsu, Zhejiang, Hubei, and Hunan, people did the same thing they did for Wu Zixu—threw dumplings in the water—in the hopes of saving Qu Yuan’s body from the nibbling fish.

Though living two centuries apart, Wu Zixu and Qu Yuan died on the same day, the fifth day of the fifth lunar month. The date of Wu Zixu’s death might be accidental, but some believe that Qu Yuan’s was intentional, including Liu Shilin, associate director of the Miluo Municipal Qu Yuan Memorial. He argues that the Duanwu Festival was originally a day to worship dragons, which were believed to have the power either to cause or to prevent natural disasters. Qu Yuan, who was so proud of his birth in the year of the dragon, would most probably choose a day of dragon worshiping to die so he could be carried into heaven by this magic animal.

The tradition of dragon boat racing is said to be 2,500 years old. The first written record of a dragon boat was excavated from the tomb of King Xiang (reigned 318–296 BCE).
The Legend of Duanwu jie

Qu Yuan’s patriotism deeply touched his people, and his death equally saddened them. Now the only thing they could do to pay their tribute was fish his body out for a proper burial. The Chinese believe that without a body, the soul will have no place to rest in. They raced against time, hoping to retrieve Qu’s body before fish could get hold of it. Suddenly someone came up with the idea of throwing cooked rice wrapped in bamboo leaves into the river so that fish would no longer feed on the body.

The day Qu Yuan died fell on the fifth day of the fifth Chinese lunar month, which has become a festival commemorating him. The rice dumpling, known as zongzi, has become part of the festival’s observance. The act of fishing Qu Yuan’s body has evolved into a tradition of boat racing, and for this reason the day is also called the Dragon Boat Festival.

Drama
Xiqū 戏曲

Chinese drama—the combination of song, dance, and music creating a whole greater than the sum of the parts—first appeared in the courts of the Zhou dynasty (1045–256 BCE) and has evolved steadily ever since, employing comedy and tragedy for the enjoyment of rich and poor alike.

The key Chinese theatrical aesthetic of melding into a singular whole the skills of singing, dance-acting, stage combat, and speech techniques with the use of costuming, props, and dramatic storytelling began in court ritual as early as the Zhou dynasty (1045–256 BCE). Drawing on the primary theatrical developments—variety shows (baixi 百戯) in the Han dynasty (206 BCE–220 CE), popular skits and Buddhist storytelling (bianwen 变文) in the Tang dynasty (618–907 CE), and variety plays (zaju 鐵劇) in the Song (960–1279) and especially in the Yuan (1279–1368), when multi-act plays of literary richness and newly-honed actor skills came to the stage—traditional Chinese opera (xiqū 戏曲) developed in the Ming (1368–1644) and Qing (1644–1912) dynasties to produce nearly 400 regionally-distinct forms. Spoken drama (huaju 話劇) and “New Theatre” (xinju 新劇) reflected Western influences on dramatic form at the beginning of the twentieth century; the years since 1976...
have seen multiple theatrical exchanges between China and other nations.

Chinese drama has a long tradition. Generally, the highly developed structure of dramatic text created in the Yuan dynasty is considered to have influenced later traditional theater literature. The Yuan dynasty is often cited as the age in which Chinese drama began. Dramatic influences on Yuan drama, however, go back many centuries, beginning in the earliest courts of record during the Zhou (1045–256 BCE).

Drama during the Zhou Dynasty

One of the most important elements of Chinese drama—the performance synthesis of song, dance, and music—first appeared in the Zhou courts. The Liji (Book of Rites) describes performance synthesis as the inherent, correlative relationship between music, movement, emotion, and other aspects of performance wherein the sum of the parts creates a greater whole. Throughout Chinese theatrical history, the aesthetic of melding into a singular whole the skills of singing, dancing, acrobatics, special speaking techniques, and use of costuming, props, and dramatic storytelling has been an identifying feature. Both the Zhou court ritual dance dramas and some of the acts staged by court jesters featured performance synthesis as an inherent element of the dramatic basis of their presentations.

Drama during the Qin and Han Dynasties

In the Qin (221–206 BCE) and Han (206 BCE–220 CE) eras, the court ritual of the Zhou was assumed for new purposes, although quite likely revised, and new forms of dramatic entertainment arose in both the countryside and urban areas. Two of the most important forms were based on popular stories. In the dramatically enacted combat scenario of chiyouxi, or Chi You theater, one finds the epic myth of the cosmic battle between the demonic rogue Chi You and the Yellow Emperor (the legendary founder of the Chinese empire). In the second skit, Donghai Huanggong (Duke Huang of the Eastern Sea), a drunken shaman is overpowered by a tiger and killed after displaying a series of magical acts. These dramatic pieces, as well as others, were often performed as part of enormous variety shows (baixi, hundred acts) staged by the courts as part of expensive displays intended to impress foreign envoys. They took the form of circus-like entertainments with costumed performers singing, dancing, and playing musical instruments among equestrian, acrobatic, and magic acts.

Drama during the Tang Dynasty

During the Tang dynasty (618–907 CE), such skits as Donghai Huanggong continued to be popular presentations in the marketplaces, at court, in temples, and in the homes of patrons. Other favorite dramatic sketches of the Tang included Tayaoniang (Singing-Stepping Woman), in which male and female actors employed song and dance to comically portray the plight of a battered woman married to a drunken, egotistical official. In another favorite, Botou (Setting Matters Right), a son mourns his father, killed by a tiger while journeying through some mountains, using a mixture of monologue and conventionalized movement patterns to portray the father’s ill-fated trip. Similar to these entertainments was canjunxi (adjutant theater), wherein two actors enacted a comic scenario about a corrupt official who steals bolts of silk.

Also during the Tang period, Buddhist monks began to dramatize sermons with the aid of scrolls illustrating Buddhist teachings. This form was called bianwen, or transformational tales, and exhibited not only religious but also historical and social or political contemporary themes. All topics were presented through a mix of literary and vernacular styles, using song, prose, verse, and idiomatic speech. Additionally, chuanqi, or marvel tales, a more literary form composed of short stories with dialogue, originated during the Tang dynasty and initiated a greater interest in using literary stylization in the dramas of developing theatrical forms. Puppet performances may have also played a significant role in the evolution of drama at this time.
Drama during the Song Dynasty

During the Song dynasty (960–1279), dramatic developments began to take place that would distinguish northern from southern forms until the present day. Song zaju (miscellaneous theater), popular in both the north and south, included on a much smaller scale some of the variety-show characteristics found previously in Han baixi. But the primary focus of the presentation was on a central play or sketch. By the time of the Southern Song dynasty (1127–1279), Song zaju was composed of three parts: a curtain raiser, the main comedy, and a comic or variety-show act. A variation of early zaju, known as southern theater (nanxi), also developed at this time, as did ballad forms such as daqu (great song set) and zhugongdiao (various palace tones), which, using direct speech rather than description, alternated song and speech. The Mongol Jurchen Jin dynasty (1125–1234), operating in the north while the Southern Song continued in the south, developed yuanben (courtyard literature), instigating a tradition of crafting texts through writing guilds that collectively worked to craft their scripts of words, song, and music.

Drama during the Yuan Dynasty

Drama flourished during the Yuan dynasty (1279–1368). Some historians theorize that this resulted when the many unemployed literati, ousted from court office in the Mongol conquest and the subsequent political shift against Confucianism, used their free time to write dramas to attack the new government. Yuanben continued in the northern courts, but the most important form to evolve was that of Yuan zaju. The writing guilds of the court infused tremendous literary breadth into zaju, and the compositional form encouraged further development of actor technique, especially in singing. Yuan zaju was divided into four acts, each featuring a soloist. Every act contained several songs, all in a single key, giving the acts a musical unity. Metrical rules were set for the alternation of prose and poetry, with over 80 percent of the ends of lines rhyming. Each act, however, had a rhyme scheme differing from that of the other acts in the play. Additionally, a wedge (a simple song of one or two stanzas) could be placed between acts. Although the song sets (qu) were a primary element, the plots and dramatic dialogue were also rich. Plays often contained forty or more acts and could have been staged in their entirety only over several days. The length of such scripts has strongly influenced presentation until this day. Most modern performances stage only highlights of a drama instead of performing the whole story. In the south, nanxi continued to develop, employing duets and trios to present the alternating lines of sung and spoken dialogue.

Drama during the Ming and Qing Dynasties

In the Ming dynasty (1368–1644), various forms of music were combined with dramatic features of pronunciation, rhyming patterns, and regional singing fashions (alternating song and speech was a common motif), producing new forms. The dramatic texts for these forms included song and musical scores. Some plays were shared, but altered, between forms. Kunqu (Kunshan opera) evolved in this age and is still performed by five
major troupes located in both the north and south of modern China.

In the Qing dynasty (1644–1912), musical systems continued to be melded with regional songs and stories to produce forms such as Beijing Opera, now performed by hundreds of professional and amateur troupes. Between 1895 and 1905, plays using Western themes and traditional Chinese performance forms were introduced and called New Theater (xinju or xinqu). An example is Liang Qichao’s Xin Luoma (New Rome) staged in kunqu form with a theme relating the contemporary government to that of the Italian risorgimento (the nineteenth-century political movement toward Italian unity and the formation of a nation state), with the characters of Dante and Cavour quoting Confucius and Tang poetry. Huaju (spoken drama), essentially Western nonmusical drama, was then imported and translated into Chinese, with favorites being works of Brecht, Shakespeare, and Chekhov. Chinese authors, such as Cao Yu and Lao She, wrote their own plays using this dramatic style.

**Drama in the People’s Republic of China**

During much of the Cultural Revolution (1966–1976), theater was banished except for eight plays and one ballet. The plays, focused on concerns of workers, were performed in the style of traditional opera but without its elegant costuming. In 1972 the ban on theater was lifted, with traditional and new performances again becoming significant aspects of Chinese culture.

After the 1976 fall of the Gang of Four (the four administrators held responsible for implementing the Cultural Revolution, including Jiang Qing, Mao Zedong’s wife), the “model” operas of the Cultural Revolution were no longer performed. During the next ten years, an open-door policy initiated an influx of foreign drama and theatrical personnel into China as well as an opportunity for Chinese artists to bring Chinese opera to America and Europe. Arthur Miller directed Death of a Salesman in Beijing in 1983, and the Shanghai Kunqu Troupe toured Europe with a kunqu-styled production of Macbeth in 1988. Dramatic developments focused on experimental and social-problem plays. A Jia and other theorists began to elaborate on the result of combining Western schools of acting, especially the Stanislavsky method, with traditional Chinese drama form and with artistic elements taken from ancient Chinese poetics and painting. The result is an evolving style of drama, uniquely Chinese, combining realism and well-defined characters with performance techniques that focus on the actor’s presence.

Many of China’s new works have developed under the auspices of major institutions, such as the Beijing People’s Art Theater. Outside the opera centers in Beijing and Shanghai, Wei Minglun’s absurdist chuanju (Sichuan opera) production of Pan Jianlian, which reexamines the eponymous, traditionally evil heroine through the varying viewpoints of several historical figures, has won international recognition as well as exerting considerable domestic influence. China’s minority groups have also actively produced works of their own. Two well-recognized productions are The Battle of Potala Palace, by the Tibet Autonomous Regional Drama Troupe, and Hello, Standard Bearer, by the Inner Mongolia Autonomous Drama Troupe.

Dream of the Red Chamber is universally recognized as China’s greatest novel. Written primarily by Cao Xueqin (c. 1715–1764), this semi-autobiographical novel combines deep psychological insight with sharp social satire, all set in a Buddhist-Daoist mythological framework that emphasizes the futility of human desire, the impermanence of all things, and the complex interplay of illusion and reality.

Cao Xueqin was born into a Chinese family of bond servants for the Manchu rulers. His great-grandfather, Cao Yin, was a personal servant of Emperor Kangxi (reigned 1662–1722), one of the highest officials of the land. However, early in Xueqin’s youth the emperor died, and his successor, the Yongzheng emperor (reigned 1722–1736), turned against the Cao family, stripped its members of their official posts, and confiscated their wealth. The family fortunes took a brief turn upward after the death of the Yongzheng emperor but suffered another purge in 1739. From that time on Cao Xueqin lived in obscurity and poverty in Beijing, where he soon began working on his novel.

Creation of the Novel

Cao Xueqin had a few close friends who appreciated his gift for vivid description and imaginative writing, and he circulated chapter drafts to some of them as he wrote (the novel in its earliest version was called Story of the Stone). One of his relatives, who identified himself as “Red Inkstone Studio” (Zhiyan zhai), made extensive marginal comments on Cao’s manuscript, which Cao himself revised five times before he died in 1764, by which time he had completed at least eighty chapters. Almost three decades later, in 1792 Gao E and Cheng Weiyuan published the first printed version of the newly titled novel, Dream of the Red Chamber, in 120 chapters. They claimed they had found a draft of the last forty chapters and had simply edited them into their final form. There has long been a controversy over the authorship of these last forty chapters, but since the late eighteenth century the 120-chapter version as published by Gao E has been the generally accepted version of the novel. The identity of Cao Xueqin as the novel’s principal author was established only in the twentieth century.

Jia Family: Prosperous but Precarious

Cao placed his novel in a mythological framework emphasizing the Buddhist message of the impermanence of all things, the dangers of emotional attachments, and the illusory nature of wealth and high rank. The story focuses on the large, prosperous, and prominent Jia family, whose high position is threatened because most of the men in the younger generation are wastrels with little or no chance to succeed in the all-important civil service examinations. The main protagonist of the story is a young boy who was
named Baoyu (Precious Jade 寶玉) for the precious jade stone found in his mouth when he was born (hence Cao’s original title). Baoyu is often chastised by his stern Confucian father, Jia Zheng 賈政, who desperately wants him to grow up, succeed in the examinations, and continue the family tradition of service in officialdom. Baoyu hates the insipid eight-legged essays (named after the rigid format of eight sections in parallel prose) required in the examinations, and he is literally sickened by the pressures placed on him to memorize the Confucian classics all for the sake of examination success and an official career. Most of the time he manages to avoid studying the classics because he is constantly indulged by his doting grandmother, the matriarch and dominant personality of the Jia family.

Idyllic Life in Grand-View Garden

Baoyu is an odd boy (most likely a self-portrait of the author) who much prefers the company of girls over boys, and he spends most of his time playing with his beautiful young female sisters and cousins and their many personal maids. When Baoyu’s eldest sister, Yuanchun 元春, an imperial concubine, is allowed to visit her family for the one time in her adult life, the family builds a beautiful “Grand-View Garden” — full of rocks, streams, trees, and pavilions — to welcome her. (This parallels events in the Cao family, who once built an elaborate garden to welcome the Kangxi emperor himself on one of his southern tours.) On her visit Yuanchun urges Jia Zheng to let Baoyu and his sisters and female cousins make their home in the idyllic garden. Many chapters in the novel are devoted to lovingly detailed descriptions of the carefree lives of these young people in the garden, where they observe the beautiful changes of the seasons and entertain themselves with frivolous games, poetry, drama troupes, painting, embroidery, and the finest food and drink that money can buy.

Tragic Love and Decline of the Jia Family Fortunes

Over time the charmed lives of these young people are spoiled by the intrusions of cold reality. Baoyu falls in love with one of his cousins, Lin Daiyu 林黛玉 (Black Jade), who moves into his family compound after her mother dies. These two are portrayed as reincarnated divine beings whose love is predestined, but their love is tragic as they are not allowed to marry because Daiyu is judged by the senior women in the family to be too frail (she suffers from what appears to be tuberculosis) and too temperamental to be considered a good wife for Baoyu. Instead he is married to another beautiful cousin, Xue Baochai 薛寶釵 (Precious Clasp), who is much more robust and cheerful than the morose but talented Daiyu. The young maids and servants of the household meet their demises through disastrous arranged marriages, suicide, or even kidnapping.
Multilayered Complexity

While the romantic triangle of Baoyu and his two lovely cousins is a central theme of the novel, it by no means dominates the story, which includes over four hundred vividly drawn characters. No novel in the Chinese tradition portrays so many characters with such psychological depth and intimacy as Dream of the Red Chamber—servants are as lifelike and individualized as their masters. Dream of the Red Chamber is a paragon of philosophical ambition and multilayered complexity. The complexity begins with the language of the novel in which puns are ubiquitous and multiple meanings can be found on every page. Great tension exists between the Buddhist-Daoist framework of the novel, which emphasizes the illusory quality of sensory experience and emotional attachments, and the strong emotional commitment of the author to his characters and their loves, hopes, and vulnerabilities.

Interpretations and Significance

Dream of the Red Chamber has been variously read as: a stinging critique of Chinese society; the anti-Manchu cry of a Chinese patriot; a demonstration of the wisdom of the ancient Chinese classic divination text, The Book of Changes (I Ching 易經), as seen through the ceaseless cyclical alteration of opposites; a tribute to romantic love however tragic; a demonstration of Buddhist-Daoist awakening to the illusory nature of sensory experience and the dangers of emotional attachments; and a profound affirmation of the power of art to give shape and meaning to the chaos and disappointments of life that might otherwise end in despair and meaninglessness.

In the twenty-first century many critics have championed each of these views and more. No other Chinese novel has inspired half as much discussion and debate as Dream of the Red Chamber. The field of Red Studies or “Redology” (Hongxue 紅學) has spawned hundreds of books, thousands of articles, and even an encyclopedia devoted to the novel. As with Shakespeare in the English-speaking world, Proust in French literature, or The Tale of Genji in Japan, Dream of the Red Chamber has achieved an iconic status as the greatest and most illuminating work of fiction in all of Chinese culture.

DU Fu

Dù Fǔ 杜甫

712–770 CE  Tang dynasty poet

One of the most prominent and influential of Chinese poets, Du Fu expanded the reach of poetic expression to include morality and history, along with literary concerns. He is often referred to as the “Chinese Shakespeare.”

The “golden age” of China is often associated with the Tang dynasty (618–907 CE), especially with the reign of Emperor Xuanzong and three eminent poets: Wang Wei, Li Bai (also Li Bo, Li Po), and Du Fu. Whereas Wang Wei and Li Bai wrote during the apex of the Tang period, Du Fu lived through the eventual destruction of this golden era.

Du Fu was born in Luoyang, in Henan Province, to a family of scholar-officials. From his earliest days, as was typical for a young man of his class, his education involved the rigorous study of the works of Confucius, the honing of writing skills, and the perfecting of poetry composed in various formal meters.

Once such an education was deemed complete, the student was faced with the challenge of taking the imperial civil service examination. Those who passed became the younger generation of scholar-officials. At this time few people were literate, given the complexity of the classical Chinese writing system; thus the pool of scholar-officials was small. Because their skills were greatly needed, scholar-officials were often found at the center of courtly life. However, such was not to be Du Fu’s life. He took the official examinations twice and failed both times. This made life difficult for him, since he was trained in a vocation that had its proper function within courtly life. So he took up literary pursuits, supported by family and friends.

Evidence from his poems suggests that it was during this period that he met Li Bai, who was a renowned poet by this time. However, Li Bai appears not to have assisted...
in furthering Du Fu’s career at court. At the age of thirty-four, Du Fu married and would eventually have five children. His hardships continued until at last he succeeded in securing a minor court position. But political turmoil soon engulfed his world.

In 755 the An Lushan rebellion, which would last for eight long years, began. The Emperor Xuanzong abdicated and fled to Sichuan. Du Fu and his family were captured by the rebels but managed to escape to Yin-chuan, in Ningxia, where Suzong, the son of Xuanzong, had been declared emperor by the royal army. But the new emperor cared little for Du Fu and gave him a very minor post. This led to much resentment on the part of Du Fu, who eventually left the emperor’s service in 760.

He spent time wandering about until he came to Chengdu, in the Sichaun province, where he took up residence in his famed “thatched cottage,” where he wrote many of his poems. His poetry is unique in that it is filled with Confucian ideals, as well as personal concerns. This allowed him to examine the plight of the individual in the wider flow of history.

His financial woes were allayed by the kindness of friends, chief among them the governor of Chengdu. When the rebels were finally driven from his native city of Luoyang by the royal army in 762, Du Fu eagerly set out, intending to return and live there once again. But his life of deprivation had taken its toll, and he suffered from various ailments, making travel slow and often impossible. He died in 768 at Changsha, in Hunan province, just as he set out once more for Luoyang.

*Shuǐ wǎng dīchù liú, rén wǎng gāochù zǒu*
Duilian (antithetical couplet, or two lines created in opposition to each other) is a Chinese literary form that follows rigid rules and has a capacity for great variety. While writing duilian requires a high level of literary skill, matching the first line of the couplet with the second can be very entertaining.

Couples are used in many cultures, such as the English sonnet, the Arabic gasida, and the Chinese lüshi (regulated verse). A couplet is a pair of lines of rhymed verse, usually having the same meter. It can be used either alone or as part of a poem. Duilian, nicknamed duizi, is an antithetical couplet peculiar to the Chinese culture and made possible by the special properties of hanzi, or Chinese characters, which are tonal and single-syllabic.

Duilian must satisfy a series of rigorous requirements in addition to rhyming and metering. Firstly, the juxtaposed lines of a duilian must have exactly the same number of Chinese characters and be punctuated in the same place. Secondly, the corresponding characters in both lines must have the same parts of speech. That is, a notional word must correspond to a notional word (such as noun and verb), and a function word must match a function word (such as a conjunction or preposition). Thirdly, level and oblique tones of the corresponding characters must not be the same. By convention, the first line must end with a character with the oblique tone while the second ends with the level tone. Lastly, not only are the meanings of both lines related, but the meaning of each matching character must be related as well. The following is an example of a duilian that meets all the requirements.

Hái (sea) kuò (vast) píng (allows) yú (fish) yuè (jump);
Tiān (sky) gāo (high) rèn (enables) niǎo (bird) fēi (fly).

The meaning of this duilian is “A vast sea allows fish to jump as freely as the deep sky enables birds to fly.” The connotation is “The only limit is oneself.”

There is no limit to the length of a duilian. It can be eight characters short or hundreds of characters long. The longer it is, the more difficult it is to write. The most famous is the 180-character duilian found in the Da Guan Garden of Kunming in Yunnan Province, China. Duilian is also found in Japan, Korea, Singapore, and Vietnam due to cultural diffusion.

Origin and History

Prototypes of couplets appeared in China as early as 3,000 years ago. Dui’ōnju (antithetical sentences) of the Shang (1766–1045 BCE) and its subsequent dynasties, pianliju (parallel and ornate sentences) of the Cao Wei (220–265 CE) and the following dynasties, and gelüshi (metered poems) of the Tang Dynasty (618–907 CE) all had a part in nurturing the growth of duilian.

Duilian became chunjian, or Spring Festival couplets, with the intervention of the early Chinese belief in the exorcizing power of the peach tree. Liji (Classic of Rites),
one of the five classics of Confucian canon, compiled in the first century CE, first mentioned the use of the peach tree to expel evil ghosts at a funeral. According to mythology, a huge peach tree on an island extended its branches a few thousand miles to the gate of a cave where devils lived. Under the tree were two god generals named Shen Shu and Yu Lü. Whenever they caught a devil hurting people, they would tie it up and feed it to a tiger. From the Zhou Dynasty (1045–256 BCE) on, Chinese began to hang a peach-wood board a few inches long on each side of their doors. Written records of the Tang Dynasty show that these boards were called taofu (peach signs). Later, the names of the two god generals were written on the wood boards and their images were drawn on them. From this practice, there came the tradition of worshiping God of Gates—a practice that still persists today in rural China.

At the same time, the evolution of the purportedly potent peach-wood board took another turn with duilian (antithetical couplets) inscribed on it. This transformation was attributed to Meng Chang, King of Later Shu of the Five Dynasties and Ten Kingdoms Period (907–960 CE). He wrote a couplet on the wood boards, which reads, “A New Year welcomes more happiness; A good festival greets a long spring:”

Xīn (new) nián (year) nà (receives) yú (more) qìng (happiness);
Jiā (fine) jié (festival) hào (calls) cháng (long) chūn (spring).

Though not a perfect antithetical couplet, it was allegedly the start of duilian in Chinese history.

Credit for putting duilian on paper is given to Zhu Yuanzhang, the first emperor of the Ming dynasty (1368–1644 CE). It is recorded that after he chose Jinling (today’s Nanjing) as the site of the dynasty’s capital, he decreed that all his subjects put up paper duilian (known as chuntie at the time) on their doors so that he could have the fun of inspecting them from door to door.

**Types of Duilian**

The name of a duilian has to do with where it is used: Yinglian is hung from the principal column of a hall; menlian, or mendai, is pasted on the door; and zhongtanglian is suspended in a parlor. As far as the occasion is concerned, helian is used for congratulation; zenglian, for eulogy; wanlian, for mourning; and chunlian for the Spring Festival, or Chinese New Year. Usually pasted vertically on the doorframes, chunlian is also menlian (door couplet) in nature. And chunlian is always complemented with a four character hengpi (horizontal scroll) pasted on the beam over the door. It serves as a summary of the couplet.

In terms of its artistic quality, there are about a dozen kinds of duilian. Diezilian has the same character occurring continuously; fuzilian has the same character repeating
itself every other character(s); dingzhenlian has the first character of the second line repeating the last of the first line; qianzilian embeds some proper nouns, such as the name of a person or a place; chaizilian has compound characters split into individual characters that form them; yinyunlian employs homophones, homographs, and words of assonance; xiequlian contains a lot of humor; wuqingdui has rigorously antithetical lines not at all related to each other in meaning; and huiwenlian is like a palindrome, meaningfully readable from either end.

**Duilian and Knowledge**

The creation of a good *duilian* requires great learning and wisdom. It also brings enjoyment to the creator as well as the reader. There are many anecdotes and legends like this:

When one of China’s greatest scholars, Ji Xiaolan (1724–1805) was young, he had an unpleasant private teacher whose surname was Shi (stone). One day, Xiaolan pulled out a brick from a wall and hid a sparrow in the hole, feeding it between class meetings. When the teacher found his secret, he killed the bird and replaced the brick in the wall, where he inscribed a line of verse:

“Xi (thin) yù (feather) jiā (domestic) qín (fowl) zhuān (brick) hòu (behind) sì (die),” meaning “A fine-feathered domestic bird is dead behind a brick.”

Seeing the dead bird and the verse, Ji Xiaolan realized what had happened. He added a second line beside his teacher’s:

“Cū (thick) máo (hair) yě (wild) shòu (beast) shí (stone) xiàn (front) shēng (live),” which means “A coarse-haired wild beast is alive before a stone.”

Seeing this, the teacher was furious, because “is alive before a stone” was a pun for “Master Shi.” Ji Xiaolan argued that he had no alternative but to match his verse word for word, as the rule of writing a *duilian* required. In his witty and learned way, the young Xiaolan avenged his lost sparrow.

Reading and writing *duilian* is part of the curriculum of Chinese schools. Providing the second line of a potential *duilian* to match the first line given is a fun game to play and is a feature of many Chinese entertainment shows, including the annual Chinese New Year celebration TV gala, which is watched by a billion viewers.

*China changes constantly, and the Encyclopedia of China will change and grow, too. Berkshire’s authors and editors welcome questions, comments, and corrections: china.updates@berkshirepublishing.com.*
Dujiangyan (The Weir on the Capital River) is a 2,300-year-old hydrological engineering works situated in the middle reaches of the Min River, the largest and longest of the Yangzi (Chang) headwaters. It is the oldest surviving water management system in the world, initially built by the Qin kingdom as a strategic element in defeating its rivals to the north and south.

Dujiangyan (The Weir on the Capital River) is a huge irrigation system located at the western edge of the Chengdu Plain, where the waters of the Min flow from a gorge to an alluvial fan plain. The Dujiangyan system is located at the highest point of the plain, allowing the whole irrigation network to run by gravity. Prior to the construction of Dujiangyan in the fourth century BCE, the natural course of the Min River followed the edge of the western foothills, and its unregulated spring flow caused massive floods. Dujiangyan regulated the floodwaters and diverted the river into the middle of the Chengdu Plain. Its canal system irrigated 126,000 ha during the Han dynasty (206 BCE–220 CE), and that capacity has expanded to almost 660,000 ha in thirty-six counties today. It has made the Chengdu Plain into one of the most dependably fertile and densely populated agricultural regions in the world. Still functioning as designed in the third century BCE, the Dujiangyan system consists of three primary and interrelated components that regulate the flow of water into the Chengdu Plain while preventing flooding and silt buildup.

As the Min River flows downstream, the Yuzui (Fish’s Mouth) levee splits it into an inner and an outer channel. The outer channel, following the original course of the river, discharges excess water, while the inner channel leads to the irrigation canals. Surface water flows into the concave inner channel, while the deeper silt-carrying water flows into the convex outer channel and can be easily dredged. The Baopingkou (Precious Bottleneck) culvert cuts through the rock face of Mount Yulei and is the gate to the inner channel. It prevents excessive water from entering the Chengdu Plain by diverting it over the Feisha (Flying Sands) spillway and into the outer channel. The Feisha spillway is located at the downstream end of the Yuzui levee. During flood season, when the water level in the inner channel exceeds a fixed point, surplus water and silt flow over the Feisha spillway and into the outer channel. The spillway discharges more than 90 percent of the silt carried in the river. During the peak farming months, when water flow in the inner channel is low, the Feisha spillway blocks water from entering the outer channel and ensures that it is available for irrigation.

Annual dredging and maintenance has been essential to the operation of Dujiangyan since its construction. During autumn, when the flow of water is at a minimum and the farm season is slack, workers create temporary diversion dams to direct all of the water into the inner channel. The bed of the channel is cleared, and any necessary repairs are carried out. In February, the dams are erected in the inner channel, and the outer channel is dredged. Branch canals are maintained by the farmers themselves. The entire
Dujiangyan system has historically been built from locally accessible and easily assembled materials, though these have been replaced by concrete since the 1960s.

**Dujiangyan and Chinese History**

It is no exaggeration to say that the creation of Dujiangyan allowed the Chinese Empire to be unified for the first time. In 316 BCE, the armies of the kingdom of Qin, one of several contenders for dominance in north China, drove the state of Chu out of Sichuan. The Qin rulers recognized that in order to prevail against their northern rivals, they would have to produce enough food to field vast armies capable of wearing down their opponents; while to eliminate Chu in the south, they should mount attacks by riverboat. The construction of Dujiangyan was the key to both of these strategies.

In 277 BCE, Sichuan governor Li Bing was commissioned to conduct an extensive hydraulic survey and build a waterworks on the Min. Tens of thousands of workers hauled bamboo baskets filled with rocks into the middle of the river, and the Yuzui levee was completed in four years. It took eight more years to cut through the mountain to create the Baopingkou culvert, using controlled fires to heat the rocks, and then dousing them with cold water to crack them. Dujiangyan was completed after fourteen years of labor by local residents, Qin colonists, and subjects of defeated Qin rivals. Timber was floated down the newly navigable river to a shipyard in Chengdu to construct warships. Additional irrigation canals transformed the Chengdu Plain into fertile farmland, and more than 100,000 people from the Qin heartland moved to Sichuan, which quickly became China’s largest granary. In 223 BCE, Qin troops sailed down the Min River from Chengdu, defeating the state of Chu. Two years later, Qin armies in the north, bellies full of Sichuan rice, unified the north. The king of Qin renamed himself as the First Emperor, initiating China’s imperial era.

The system continued to expand throughout the imperial era. As governor, Li Bing staged a ritual confrontation with the dragon spirit of the Min River, long revered by locals. By the Han dynasty, some people came to believe that Li Bing himself had become a god, commemorated for vanquishing the dragon spirit and ending human sacrifices to it. During the Song dynasty (960–1279), civil officials, committed to extending cultural
conformity throughout the empire, reinvented Guankou Erlang, an ancient Min River water-taming god who still commanded sacrifices of 40,000 sheep each year, as a Confucian official and son of Li Bing. Finally, it was at Qingcheng Mountain overlooking Dujiangyan that centenarian hermit Zhang Daoling is said to have ascended to heaven as an immortal in 143 CE. His successors transformed Daoism from a set of philosophical principles into a sectarian religion under the Heavenly Master school. Most of the original twenty-four dioceses of Heavenly Master Daoism are located in and around the watershed of the Dujiangyan irrigation system.

Dujiangyan Today

Since 2000, Dujiangyan and Mount Qingcheng have together been inscribed as a UNESCO World Heritage site drawing almost a million visitors each year. Dujiangyan remains the key to intensive agriculture in the Chengdu Plain, which supports an urban and rural population of more than 15 million people and boasts one of the world’s highest rural population densities. In recent years, a number of hydroelectric projects have been completed on the Min River. There are currently fifteen dams in operation or under construction on the river. These dams, which critics believe may constrain urban and agricultural access to water and threaten the continued viability of Dujiangyan, are controversial both in China and internationally.

The Dunhuang Caves include three sites of Buddhist cave shrines located near the desert oasis city of Dunhuang. Decorated with spectacular wall paintings and sculpture, and once the repositories for a treasure trove of Buddhist texts (such as the Diamond Sutra, now in the British Museum), the caves were added to the list of UNESCO’s World Heritage Sites in 1987.

The Dunhuang Caves are three sites of Buddhist cave shrines located near the city of Dunhuang, a desert oasis lying on the ancient Silk Roads: the Western Qianfodong 西千佛洞 (Western Caves of the Thousand Buddhas), located approximately 3.2 kilometers west of Dunhuang; the Yulin Caves 榆林窟, located approximately 168 kilometers east of Dunhuang; and the Mogao Caves 莫高窟, the most important site, located approximately 40 kilometers southeast of Dunhuang.

The most extensive surviving early Chinese Buddhist material culture is found at the cave temples of Mogao. Here, beginning in the early fourth century and continuing for the next one thousand years, more than one thousand caves were hollowed out of the cliff face at the edge of Mingsha (Dunes of the Singing Sands). Nearly five hundred of the caves are decorated with spectacular sculptures and wall paintings. In 1900 a hidden cache of nearly fifty thousand documents was discovered in what came to be known as the Library Cave, which had been sealed in the early eleventh century. Found in this treasure trove of material was a copy of the Diamond Sutra; its date of 868 makes it the world’s oldest printed text (a sutra is one of the discourses of the Buddha that constitutes the basic text of Buddhist scripture). Also found in the Library Cave was a variety of art forms that includes paintings on silk, woodblock prints on paper, calligraphy, and embroidery.

The site for the Mogao Caves was selected by the wandering monk Yuezun, who set out to excavate the first caves in 366 after beholding the golden glow of one thousand Buddhas floating there, giving rise to the site’s alternate name of Qianfodong (Cave of the Thousand Buddhas). These early caves were used for meditation, but in time they also served as a monastery and a religious center. Decorating of some of the caves came soon after Yuezun’s initial work. The caves contain wall paintings of spectacular beauty. Life-size sculptures were added, but because the stone at Dunhuang is too friable (easily crumbled) and not suitable for sculpture, they were fashioned from clay formed over a wooden armature and then painted.

The history of the caves is also a history of invasions. Central Asian influence on the caves was the result of Arab conquests in the mid-eighth century. The occupation by Tibet, beginning in 781 and lasting until 848, resulted in new caves painted with Tibetan Buddhist iconography. The Tibetans also protected the site from the strong anti-Buddhist persecution in 845 that had a profound effect on the rest of China. In 1006, when Islamic armies from Kashgar conquered the Buddhist city of Khotan, fear that Mogao would soon be next likely prompted the monks to seal thousands of manuscripts in the cave. However,
Islamic culture would not reach Dunhuang until after the invasion of the Mongol conqueror Genghis Khan’s army in 1227, which destroyed the city. Artistic activity continued under the Mongols until at least 1357 owing to favor that Tibetan monks had at court. After the fall of the Mongols, Arab armies controlled central Asia, and Islam became the dominant religion, effectively ending work at the caves. As traffic along the Silk Roads declined when sea travel replaced overland routes, the caves were all but forgotten and would remain so until the first years of the twentieth century.

Library Cave Found

In the 1890s the Daoist monk Wang Yuanlu (c. 1849–1931) settled at the Mogao Caves and became the self-appointed guardian of the site. While overseeing restoration work in Cave 16, he found a crack in the wall that revealed a hidden entrance to another cave. Here was the so-called Library Cave (Cave 17), which contained a wealth of manuscripts, paintings, embroideries, and banners filling the cave from floor to ceiling. In 1902 the collection was to be relocated to the provincial capital, Lanzhou, but because of the high cost of moving it, Wang was ordered to put the material back into the cave and reseal it.

In March 1907 Sir Aurel Stein (1862–1943), an archaeologist and explorer of central Asia, arrived at the site. Acting on behalf of the British Museum, Stein was awestruck by the vivid color of the murals and painted statues and referred to the site as a “wonderful beehive of temples.” Wang was at first reluctant to allow any of the Library Cave materials to be removed, but he was soon swayed by Stein, who offered contributions to the restoration of the site in exchange for the scrolls. In all, Stein left with twenty-four cases that contained thousands of manuscripts and fragments and five cases of paintings and embroideries, all of which he purchased for £130. Among his finds was the Diamond Sutra, which is now in the British Library.

After Stein came the French sinologist Paul Pelliot (1878–1943) in 1908. Owing to his ability to read Chinese, Pelliot was able to select the most scholarly and historically significant items from the material Stein had left behind. He paid £90 for the thousands of manuscripts that now rest in the Musée Guimet in Paris. Although the Chinese made an effort to limit the dissemination of Dunhuang material to foreigners, nearly six hundred documents were sold to the Japanese in 1911, two hundred to the Russians in 1914, five cases again to Stein in 1914, and twelve sections of wall paintings to Langdon Warner of the Fogg Museum at Harvard in the 1920s. Thus, the contents of the Library Cave have been scattered worldwide. In 1993 the British Library began a project to unite these objects on the Internet. The International Dunhuang Project is designed to promote the research and preservation of the Dunhuang material in an international arena.

Preservation Efforts

Today the site is in remarkable condition, given its age. The cliff face has weathered over the centuries, and the instability of the sandstone has resulted in the collapse of some sections of the caves. The wall paintings are cracked and peeling. Smoke from fires set in the caves left a layer of soot on the walls. Vandals have defaced some portions, and the presence of Stein and the others has left its mark. Still, the wall paintings and sculptures retain their brilliance. In 1944 the Dunhuang Research Institute (now the Dunhuang Academy) was established to focus on research and conservation of the site. In 1980 the caves were opened to the public. In 1988 the Getty Conservation Institute joined the Chinese in studying the deterioration of the caves and methods to preserve them. In 1987 the United Nations Educational, Scientific, and Cultural Organization (UNESCO) designated Dunhuang as a World Heritage Site.

Further Reading

During most of the recorded history of East Asia (Japan and Korea), China was the dominant force and exerted a great influence on the culture—religion, government, art, communication—of the other two nations.

In the seventeenth century, when European scholars presented their latest maps to the Chinese court, the Chinese were impressed with the scholars’ skill and technological sophistication. However, court officials were offended because China was not depicted at the center of the world. After all, historically China viewed itself as the Middle Kingdom; its centrist worldview was based on objective criteria. As late as the Ming dynasty (1368–1644), China continued to be the world’s most powerful nation in terms of population, commerce, size, wealth, technology, learning, fine arts, and literature. For most of the recorded history of East Asia (Japan and Korea) China was supreme. China was the source, not the recipient, of culture.

Periods of time have come and gone, like the waxing and waning of the moon, when Japan and Korea have resembled "little Chinas" because of their deliberate imitation of China, whereas other periods have had minimal interaction between these nations. China’s most significant influence on East Asian nations came during the early years of their recorded histories. For that reason Chinese culture remains at the root of East Asian society. Just as people are more influenced by experiences in their early years, Korea’s and Japan’s early years were marked by their acceptance of Chinese political, economic, ideological,
and social patterns. What Korea and Japan adopted during their early civilizations became the foundation for their more mature civilizations.

Migrants from northern China were among the first inhabitants of Japan and Korea, where during the first millennium BCE these migrants developed a hunter-gatherer culture. The religion of the region was animistic (relating to the doctrine that the vital principle of organic development is immaterial spirit) and had an apparent reverence for nature and ancestors. Because Korea was attached to the continent, it (more than Japan) was influenced by the political machinations of China. During its Han dynasty (206 BCE–220 CE) China directly ruled the Korean peninsula. However, early on a pattern between China and East Asia developed: When China faced internal crisis, its political influence in Japan and Korea diminished. Thus, the fall of the Han dynasty coincided with the increased power of the indigenous Korean kingdoms of Koguryo (37 BCE–668 CE), Paekche (18 BCE–663 CE), and Shilla (57 BCE–935 CE).

Economic stability, spurred by the development of rice agriculture, shifted the social structure of East Asia from a nomadic existence to a sedentary existence with geographical boundaries. As East Asian clans competed for supremacy over a particular state, they sought legitimacy for their positions by their affiliation with China. The political tug-of-war among the three native states in Korea and the emerging Japanese state of Yamato (300–552 CE) produced political hierarchies and centralized powers. The development of dominant states in East Asia coincided with the increased power of the indigenous Korean kingdoms of Koguryo (37 BCE–668 CE), Paekche (18 BCE–663 CE), and Shilla (57 BCE–935 CE).

Spread of Buddhism

India is the homeland of the Buddha. However, by the Han dynasty Buddhism was beginning to flourish in the Middle Kingdom as its influence declined in India. Buddhism continued to move eastward. In 372 CE Buddhism was introduced to the Koguryo court in Korea. The religion spread throughout the peninsula as Chinese monks proselytized throughout Korea. At the same time Koreans traveled to China to study at influential monasteries. The implications of the Korean states’ acceptance of Buddhism as the metaphysical explanation of reality were great. The ties between China and Korea were now cemented by a shared religion. The sacred scriptures of Buddhism were written in Chinese characters, and the Koreans’ wish to understand Buddhism solidified the use of Chinese as the means of written communication throughout Korea. In addition to adopting the Chinese written language (which is a significant measure of Chinese influence) the Korean states adopted the architecture and art that accompanied Buddhism. Dominant Korean art forms reflected Chinese works—palaces and temples were built according to popular styles in China.

Elements of Buddhism migrated from Korea to Japan during the fifth century, but Buddhism’s official introduction did not occur until 552. Historians note that during the first half of the sixth century the state of Paekche was at war with Koguryo and Shilla and that, in an effort to bring Japan into the war, Paekche offered to introduce a glorious new truth to the islands if Japan offered its assistance. Thus, Buddhism was introduced to the Japanese court officially through Korea. The religion was adopted by the most powerful families at the court, who were relatively recent emigrants from the peninsula. As in Korea, Japan’s adoption of Buddhism affected art, language, and architecture in Japan. Chinese written language was the modes of written communication throughout the islands; Japanese art was hardly distinguishable from Chinese art.

Buddhism’s influence on East Asia occurred from the top down. The elite families first adopted it, although eventually it moved into all social classes. The prominent states sponsored the spread of Buddhism by building monasteries and providing economic relief to those people tending the temples. The state paid artisans to create Chinese-style Buddhist art pieces, and these media filtered down to the general population. Buddhism spread throughout East Asia because indigenous religions were still evolving and lacked the sophistication of Buddhism. The elaborate rituals, scriptures, art, and mantras that Buddhism offered were accompanied by other cultural influences from China.

Mere decades after Buddhism was introduced to Japan, China was united under the glorious Tang dynasty. The states of East Asia imitated the economic and political grandeur of Tang China. In politics Korea and Japan adopted the Tang concept of the state’s supremacy and the emperor’s complete authority. In Japan this concept firmly established the still-extant imperial throne. Korea and Japan also adopted the Tang form of taxation, which
necessitated a more sophisticated way of assessing the land’s resources. The rulers of Japan and Korea partitioned their land into provinces, prefectures, and districts with the assumption that all land belonged to the state and that taxes were needed from those who worked the land. In Japan and Korea, as in China, rice was the currency of the day, and approximately 40 percent of a harvest was paid to the state. The adoption of Chinese economic and political patterns increased the political stability in East Asia. Korea and Japan, increasingly sinicized, continued to look to China for legitimacy, learning, and culture.

The degree of China’s influence during this time is shown in Japan’s so-called seventeen-point constitution, which was developed during the seventh century. The first point was the Confucian injunction that the goal of the state is to establish harmony above and friendliness below. The second point asserted that conversion to Buddhism would straighten everything crooked. In Korea academies were established just to teach the Confucian classics, and similar academies were established in Japan. The Confucian principles of filial piety and the rigid rules that govern relationships were spread through these institutions.

**Transformation of Political Institutions**

During the Tang dynasty political institutions were transformed in Korea and Japan. In Korea the government adapted the six ministries of the Tang government. In Japan the ministries of a central secretariat and the imperial household were added to the conventional six ministries of the Tang government. Chang’ an, the capital of China, was the most cosmopolitan city of the eighth century. Korea and Japan sent ambassadors to Chang’an. Not only did Korea and Japan borrow the art and architecture of Chang’an but also they laid out their capitals in the checkerboard fashion of the Tang capital. Japan during the eighth century established Nara in the
fashion of Chang’an. On the northern end of the Kyoto Plain the city of Heian was founded in 794 with dimensions of just over 5 by 5 kilometers, a bit more modest than the Chang’an dimensions of approximately 9.5 by 8 kilometers.

Japan and Korea also sought to establish a bureaucracy based on merit, as was the case in China. Japan and Korea set up positions in government structures with the understanding that the positions would be filled by men of rank. In 958 the Korean civil service exam was based on the Confucian classics, and a man advanced through knowledge of these Chinese works. However, by the tenth century an atrophy of Chinese influence was occurring in Korea and Japan. This atrophy was caused by the hard times that faced China after the fall of the Tang dynasty as well as by a fundamental shift in China’s state revenue system.

Although Korea and Japan emulated Tang China, aspects of the Chinese world did not quite fit the Korean and Japanese models. For example, China’s neighbors never fully integrated the merit-based bureaucracy system. Aristocratic families dominated the economic and political worlds of Japan and Korea, and an exam to level the playing field did negate the dominant role of the aristocrats. However, the true breakdown of the Chinese system in East Asia was caused by the increase of tax-free lands. In Japan and Korea parcels of land were given to monasteries and to families to whom the court owed favors. At the beginning these tax-free lands were minimal in size. However, they grew into enormous tax-free estates. The state could do nothing about its declining tax revenues because the estate owners either were under the patronage of the elite families or were from the elite families themselves. By the twelfth century tax-free religious or estate zones perhaps accounted for more than 50 percent of the land in Japan and Korea. With the steady decrease of revenue, the states found it difficult to respond to internal crises, particularly in trying to maintain peace in an time when marauding gangs preyed on farming villages. Villagers and estate owners turned away from the impotent state and to the warrior class for protection. Thus, the pattern of state control and a scholar-led bureaucracy subtly changed. In Japan true power moved from the imperial family to the bakufu (tent government) or military government led by the sei taishogun (barbarian-suppressing generalissimo, commonly called simply “shogun”), who was headquartered with his retainers and advisors.

Japan’s and Korea’s departure from the Chinese model in politics coincided with their adoption of indigenous written languages. The Chinese character-based written language was always a difficult fit in the Japanese and Korean polysyllabic and inflected languages. One compromise was to use Chinese characters to represent sounds rather than words. During the tenth century in Korea a system called idu—in which Chinese characters represented sounds—became the means of written communication. By the fifteenth century a Korean phonetic system known today as “hangul” replaced the Chinese character-based written language on the peninsula. In Japan the women of the eleventh-century court led the way in writing Japanese, whereas the men continued to use Chinese characters. Moreover, the literature that the men produced was inferior to that of the more adaptable, but new, Japanese written language.

During the Yuan (1279–1368), Ming (1368–1644), and Qing (1644–1912) dynasties Korea and Japan continued to acknowledge the supremacy of China in East Asia. Granted, Toyotomi Hideyoshi (1537–1598) of Japan dreamed of invading China at the end of the sixteenth century, but his irreverent approach to China was the exception, not the rule. Buddhism, especially the Chan sect from China (called “Son” in Korean and “Zen” in Japanese), greatly influenced society in art, architecture, and philosophy during the premodern era of Korean and Japan. During the Tokugawa period (1600/1603–1868) of Japan the prevailing ideology was neo-Confucian thought because it validated the division among the elite, farmers, artisans, and merchants. In Korea the Choson dynasty (1392–1910) continued to defer to China. Three times a year the “little brother” sent tributary missions (goods or money paid in deference to and with respect for China), to the “elder brother.” During the time Confucian ideology was more thoroughly integrated into Korean society than it was in China.

**Confirmation of China’s Weakness**

However, East Asian nations noticed that during two of its last three dynasties China was ruled by outsiders: first the Mongols of the Yuan dynasty (1279–1368) and then the Manchus of the Qing dynasty (1644–1912). China’s weakness was confirmed by humiliating defeats in its wars against the British during the nineteenth century. China made concessions to foreigners, and China’s undisputed leadership of East Asia was soon just a
memory. During the last half of the nineteenth century both China and Japan sought to strengthen themselves. China wanted to stave off the Western imperial countries, and Japan wanted to be a first-class nation. Japan’s lack of respect for the once-proud leader of East Asia was shown in the 1894–1895 First Sino-Japanese War and subsequent severe Treaty of Shimonoseki (1895). Korea, the pawn in the game, was forced to recognize Japanese dominion.

The First Sino-Japanese War was a precursor to a much bloodier war between the two nations. Between 1937 and 1945 China and Japan fought in the War of Resistance against Japan, known outside China as the Second Sino-Japanese War. The tragedy at Nanjing—often referred to as the “Rape of Nanjing,” where Japanese soldiers butchered Chinese civilians—showed the animosity that Japan felt toward its old tutor. Some scholars speculate that this animosity was rooted in the Japanese embarrassment and disgust that the source of Japan’s culture had sunk so low. By contrast, Korea was made part of the Japanese empire (1910–1945). The Koreans, too, were treated harshly by their new colonial ruler.

East Asia after World War II can be understood only in the light of the Cold War. Sino-Japanese relations remained sour because of the memory of Japanese brutality during the war and because the United States for decades insisted that Japan not have relations with Communist China. The Korean Peninsula was partitioned into two countries, with North Korea having warmer relations with China. However, as China emerged as a free-market state, its relations with South Korea improved, whereas North Korea continued to flounder because of its large military budget and the collapse of its once-powerful ally, the Soviet Union.

Korea and Japan have experienced a sweet-and-sour relationship with China. However, China’s influence on the two countries is beyond estimation because of the adoption of the Chinese pattern by the early civilizations of East Asia.

Transfer of Chinese Sugar-Making Technology to East and South-East Asia

Using the Chinese sugar-making technology as an example, China scholar Joseph Needham relates the importance of the transfer of technology from China to other countries in East and Southeast Asia.

In recent times concern with the transfer of Western technology to Third World countries seems to have diverted the attention of scholars away from the significant role played by technology transfer in the economic and social development of pre-modern Asia. In the following pages I will consider East and South-East Asia, demonstrating how individual States borrowed or received, a single agro-industrial sugar technology from China to aide their economic development.

As remarked earlier, domestic sugar production in China began to increase from the 16th century and expanded greatly with the immigration of Fukienese peasants to Taiwan, Chiang-Hsi and Kuang-Tung during the 17th century. Individuals or groups of people with knowledge of, or access to, all the component elements of the technological package effected the transfer and diffusion. Chinese immigrants took the package overseas from the late 16th century, and laid the technological foundations of pre-modern East and South-East Asian sugar production that lasted until the 20th century.

The East China Sea—part of the western Pacific Ocean—is China’s most important marine fishing area. The sea also has rich oil and gas reserves, but China’s exploitation of such reserves is complicated by a Sino-Japanese territorial dispute.

The East China Sea (Dong Hai) is part of the western Pacific Ocean. It is 1,296 kilometers long from north to south and 740 kilometers wide from east to west. It covers an area of 790,000 square kilometers. In the north it borders on the Yellow Sea (Huang Hai), and in the east it borders on Jiangsu, Zhejiang, and Fujian provinces of the Chinese mainland. In the south the East China Sea is connected to the South China Sea (Nan Hai) through the Taiwan Strait. The southern Japanese archipelago with the Ryukyu Islands constitutes the eastern border.

Except for an area around the Ryukyu Islands, where depths of 2,700 meters have been measured, the East China Sea is on a shallow continental shelf, most of which is less than 200 meters deep. The Yangzi (Chang) River flows into the East China Sea, leaving huge deposits of sediment. The climate is subtropical, and monsoon winds with summer rain predominate.

The East China Sea is China’s most important marine fishing area, and the catches of hairtail, small and large yellow croaker, and cuttlefish account for two-thirds of China’s total catch. Shanghai, just south of the mouth of the Yangzi River, is the largest port on the sea and also is the center for food processing.

The sea has rich oil and gas reserves, but China’s exploitation of such reserves has been complicated by a Sino-Japanese territorial dispute—sovereignty over the Diaoyu Islands. China, Taiwan, and Japan claim the eight uninhabited islets. In recent years piracy also has become a problem in the East China Sea.

East China Sea Oil Exploitation

Oil exploitation of the East China Sea is one of several complicated issues between Japan and China stemming from Sino-Japanese territorial disputes over the Diaoyu Islands. Although a tentative agreement about oil exploitation in the East China Sea has been reached by Beijing and Tokyo, the sovereignty of the Diaoyu Islands is still unresolved.

China’s exploitation of oil in the East China Sea has been complicated by a Sino-Japanese territorial issue—sovereignty over the Diaoyu Islands (known in Japan as the Senkaku Islands).

The Diaoyu Islands are located about 193 kilometers northeast of Taiwan, approximately 289 kilometers west of Okinawa, Japan, and approximately 402 kilometers east of China’s mainland. The islands are made up of eight uninhabited islets, including three barren rocks, which are claimed by China (People’s Republic of China or PRC), Taiwan (Republic of China or ROC), and Japan. Currently Japan controls the islands, which officially are under the jurisdiction of Ishigaki city of Okinawa Prefecture. Until 1968 the Diaoyu Islands were essentially worthless to China and Japan, and neither country appreciated their value. However, that changed after the Committee for Co-ordination of Joint Prospecting for Mineral Resources in Asian Offshore Areas, under the auspices of the United Nations Economic Commission for Asia and the Far East (ECAFE), reported substantial energy deposits under the East China Sea.

Based on a geological survey, experts estimated that the continental shelf surrounding the Diaoyu Islands contains 10–100 billion barrels of oil. As of 2008 neither China nor Japan has actually drilled in the disputed area as they make overlapping claims to the islands and their surrounding waters. Nor has an international solution been possible. Neither country is willing to submit the dispute to the International Court of Justice. In the current debate two competing views have emerged: A pro-China group emphasizes the use of historical evidence from the archives of the Ming (1368–1644) and Qing (1644–1912) dynasties. A pro-Japan group emphasizes the “discovery” theory in international law, arguing that the Japanese “rediscovered” the islands in 1884 as terra nullius (i.e., unadministered territory or no-man’s-land). In reality, the Diaoyu Islands have become “hostage” to the disputing parties, Japan and China, since the 1970s.

On 28 May 2004 the Japanese media dropped a bombshell on already shaky Sino-Japanese relations. The media reported that, starting in August 2003, China began to develop a natural gas field exploration project in the East China Sea—the Chunxiao oil and gas fields. The Japanese government worries that this drilling will enable China to siphon off the 1.6 trillion cubic feet of natural gas buried under China’s side of the disputed islands. Thus, the Chunxiao oil and gas fields loom as another bone of contention between Tokyo and Beijing.

Starting in May 2004, Japan and China held several rounds of bureau-chief-level talks and occasional informal negotiations in Beijing and Tokyo. Finally, on 18 June, two superpowers in the East Asian region finally settled...
the oil/gas development situation in eastern China. Two major points in this agreement:

1. both countries agreed to explore jointly a 2,700-square-kilometer area south of the Longjing oil field, stretching across the Japanese-claimed median line.

2. regarding the Chunxiao gas field, which the Chinese have already operated for years, Beijing welcomed investment by Japanese corporations in the project in accordance with Chinese laws.

However, the sovereignty issue of the Diaoyu/Senkaku Islands and the demarcation of the international boundary in the East China Sea, such as the Japanese-claimed median line and the Chinese-claimed natural prolongation line, were not addressed by this agreement.

Basically China claims sovereignty over the area of the Chunxiao oil and gas fields, which are located immediately outside the median line or the exclusive economic zone (EEZ) claimed by Japan, and has rejected Japanese requests to hand over all data about Chunxiao and to suspend drilling. Even though China proposed joint development of the disputed territory, Japan insists that it has sovereignty over the Diaoyu Islands and refuses the joint development proposal. However, Japan proposed joint development of four oil fields—Chunxiao, Duanqiao, Tianwaitian, and Longjing—which are only 10 kilometers northeast of the Diaoyu Islands. China rejected this proposal. As the Japanese government argues, one of the four oil fields crosses the median line claimed by Japan, and the remaining three are completely inside Japan’s EEZ. Yet, Beijing has refused to accept the median line set by Tokyo. Instead China has argued that its EEZ extends to the far reaches of its continental shelf, which ends west of Okinawa Prefecture. Hence, the Japanese and Chinese claims of sovereignty overlap over a large area in the East China Sea. During the fourth round of talks Beijing proposed joint development of the Longjing field, but Tokyo did not accept. Furthermore, in 2005 the Japanese government granted Teikoku Oil Co. the right to perform exploratory oil drilling in an area opposite the Chunxiao oil and gas fields.

In early 2007, after a Chinese surveillance ship was detected about 32 kilometers from the islands, territorial disputes escalated; later that year Japan formally protested China’s gas exploration in the contentious EEZ area. At landmark summit talks in Tokyo in May 2008 Chinese president Hu Jintao and Japanese president Yasuo Fukuda signed a deal that agreed to establish a “new starting point” in relations between the two nations; settling the disputes over gas deposits in the East China Sea was one of their priorities. But efforts to resolve this issue have yet to be successful and continue to complicate the nations’ other negotiations. In December 2008, shortly before Japan, China, and South Korea were scheduled to participate in an economic summit in the Japanese city of Fukuoka, Japan accused China of sending research ships to visit the Diaoyu/Senkaku Islands, and called the alleged violations “extremely regrettable.”

China abandoned a Soviet-style command economy in favor of a mixed economy late in the twentieth century, and the economic system overall contains a complex set of enterprise designations: state ownership, shareholding, private ownership, collective ownership, foreign direct investment, and public ownership through shareholding. In spite of many reforms and impressive growth during the past two decades, the economy faces major hurdles.

China’s economic system during the last two decades of the twentieth century changed from a command economy, which dated to shortly after the Communists took control in 1949 and was based on the Soviet economic system, to a mixed economy with complex set of economic relationships between enterprises and the state.

Command Economy

In a command economy the means of production are publicly owned, and economic activity is controlled by a central authority that assigns quantitative production targets and allots raw materials to production units. A command economy entails comprehensive economic planning on the basis of targets and balancing of materials.

China’s command economy was established in 1950 and 1951 and was followed by a Soviet-style five-year plan, the First Five-Year Plan, for the years of 1953 to 1957. The Soviet model was ideologically sound in the Marxist theory that supported it, but, more important, the Chinese deemed it a necessity when they had to face the decline of the economy after a century of wars and turmoil. With the capacity to mobilize resources quickly on a national scale, this administrative approach was effective in its initial phase.

Beginning in the early 1950s Chinese central industrial ministries and administrative regions were required to assign production targets to enterprises under their jurisdiction. Each group of enterprises was then required to formulate annual production, labor, and cost plans and to submit them to the higher echelons—that is, the industrial ministries or bureaus—for approval. During this period procedures for making annual plans “from the bottom to the top” and “from the top to the bottom” were introduced and standardized. Frequent consultations and exchanges of information took place at various levels of the hierarchy. Moreover, China established a centralized system of supplying raw materials.

The central bureaucracy played a major role in the economy. For example, in the industrial sector the state owned outright enterprises that produced more than 60 percent of the gross value of industrial output, and all but a small portion of the remainder was collectively owned. In the urban sector the government not only prescribed output targets and allocated energy resources but also set the prices for key commodities, ran the wholesale and retail networks, determined the level and general
distribution of investment funds, set wage levels and employment targets, and controlled financial policy and the banking system. The foreign trade system also became a government monopoly during the early 1950s. Similarly, in the countryside beginning in the mid-1950s the government prescribed the level of prices, set cropping patterns, and fixed output targets for all major crops. Most rural commercial transactions were undertaken by the Supply and Marketing Cooperatives—nominally an organization of farming cooperatives but in fact a heavily bureaucratized organization that operated as the rural branch of the Ministry of Commerce.

In 1952, in order to run the command economy, the chief organ of planning, the State Planning Commission, was established and placed under the State Council when the council was made the supreme executive body by the 1954 constitution. At the same time the State Construction Commission was established to oversee capital investment under the five-year plans in 1956; the State Economic Commission was formed to take over short-term—up to annual—plan responsibilities, leaving the State Planning Commission to concentrate on long-term and perspective planning. Also established in 1956 were the State Technological Commission to plan long-term technical development and the General Bureau for Supply of Raw Materials to handle material allocation. The State Statistical Bureau was formed in 1952, its provincial and municipal statistical departments in 1953, and below them administrative and special district officers in 1954.

**FIRST CENTRALIZED, THEN DECENTRALIZED**

The organization of planning grew more centralized, reaching a peak during 1955 and 1956. China had nearly 200,000 enterprises, operating with widely varying technologies, levels of efficiency, and product assortments, even within the same industry. However, the data gathered, transmitted, and processed for central planning were irregular, sometimes incomplete, and often overestimated. As the number of commodities and the number of enterprises for which the central planning bodies assumed responsibility increased rapidly, the maintenance of such a great degree of centralization of both planning and management...
became ever more cumbersome. In 1957 and 1958 the government adopted decentralization measures to shift some responsibilities to the localities, increase the scope for local initiative, and strengthen central control of the most important plan targets and enterprises.

During this round of decentralization most planning tasks were transferred to officials closer to the scene of production in an effort to shorten the lines of communication and to reduce absentee management. This transfer took place when the ministries passed most of the enterprises they had controlled to regional authorities, which gained more rights to allocate scarce resources. Most planning tasks then became the responsibility of regional and local authorities. This move was also a regionalization of planning by which several industrial ministries were abolished after losing a majority of their enterprises. The sixty thousand communes subsequently received an administrative and planning role in rural areas. They replaced the xiang (township governments) in 1958. In principle only the most important enterprises remained under direct ministerial control; even many of these were supposed to come under dual subordination to ministries and regional authorities. However, in practice ministerial control came to dominate. The decentralization of 1957 and 1958 was never entirely reversed.

The command economy traditionally operated with a strong centralized monopoly over commerce. Monopoly purchase of grain actually preceded agricultural collectivization, and even during the Cultural Revolution (1966–1976), when much of the industrial management system was being decentralized, central control of agricultural procurement and distribution of key consumer goods continued. Although around thirty thousand rural and suburban periodic markets (that is, markets that opened periodically) existed, they were rigidly controlled, and people were forbidden to transact goods, such as grain and cotton, over which the Ministry of Commerce had a monopoly.

The shortages seemed to come from three sources. First, the government simply channeled so many resources into investment and heavy industry that there were few left for households. Second, the soft budget constraints of enterprises caused shortages. Most enterprises were profitable, and they faced no risk of bankruptcy. As a result, they pursued unrestrained growth and had an almost unlimited desire for investment. Each planning unit of an enterprise typically tried to make sure it would have the inputs it needed to fulfill its plan targets plus a margin for insurance. Therefore, each unit tended to overstate its needs and to treat the requirements of other planning jurisdictions as residual. Third (and related to the second), when managers were promoted based on their ability to meet the state-set output volume, their demand for inputs tended to expand until total demand ran up against the total available supply of resources. The over-demand for production inputs, without much concern for quality of output or efficiency, led to constant shortage of the supply of resources. Thus command economies have a built-in tendency to become “shortage economies.”

**Social-Welfare Policy**

China’s command economy, in addition to the features mentioned earlier, adopted an urban-biased social-welfare policy to spur industrial development. The policy provided not only lifetime full employment but also virtually free housing, free health care, and free retirement benefits. However, nonurban residents were excluded, and the government controlled obtaining permits for urban residency.

The government also controlled internal migration and job assignment in the urban sector through a house-registration system, which largely replaced the free labor market after 1957, although the reforms after the rule of Chinese Communist Party leader Mao Zedong have attempted to revive it.

**Economic Reforms after Mao and a Mixed Economy**

Since the death of Mao in 1976 China has tried to reform its economy with gradual but somewhat parallel changes in the urban and rural sectors. The reforms by Communist Party general secretary Deng Xiaoping (1904–1997) have
been accompanied by complaints about the inefficiency of Soviet-style central planning and, in particular, about China’s overlapping and inefficient administrative bureaucracy, along with the excessive dependence of enterprises on their planning apparatus. In an effort to end the latter, post-Mao leaders have sought to establish a system of managerial and production responsibility under which producers become more responsible for procuring supplies, marketing their output, operating in a cost-effective manner, and financing their investments from their own earnings or repayable bank loans. In these post-Mao reforms the government has stressed raising personal income and consumption and introducing new management systems to help increase productivity. It also has concentrated on foreign trade as a major vehicle for economic growth.

China in the late 1970s began to pursue agricultural reforms, dismantling the commune system and introducing the household responsibility system, which gave peasants greater decision making in agricultural activities. Evolution of the household responsibility system can be roughly divided into three phases: the work-quota contract phase, the output-quota contract phase, and the responsibility contract phase. During the work-quota contract phase the household was responsible for the hours of work contracted on the collective land with the production input from the collective. During the output-quota contract phase the household was responsible for the quantity of output contracted given the production input from the collective. During the responsibility contract phase the household was responsible for everything from input to output. The government has also encouraged nonagricultural activities, such as township and village enterprises (TVEs), in rural areas. Thus agriculture has been decollectivized; small-scale private trade and workshops have
been legalized; and the role of market forces has been considerably increased.

In the urban sector the goal of enterprise reform becomes ever loftier. Its original goal was to solve the problems of low incentive and inefficiency in state enterprises. However, as the reform has progressed, the goal has become changing the managerial mechanism to make state enterprises competitive in the market.

**FOUR PHASES OF ECONOMIC REFORM**

Reformers in China, as in other socialist countries, have followed a dual approach. In addition to the state sector, they have allowed the more marketized sector—consisting largely of small- to mid-sized private and collective firms—to expand explosively in both rural and urban areas. In some cases the enterprise capital is still state owned, but the facilities are leased to individuals or groups who operate them on a profit-or-loss basis. Stock and bond markets have also sprung up since the mid-1990s, and more than 400,000 enterprises have incorporated themselves.

Within the planning network many large enterprises still have a primary responsibility to meet plan targets, but the targets are supposed to be set low enough to allow a margin of overfulfillment. Production that exceeds state targets or is not covered by targets is to be sold in competitive markets, and enterprises that do this successfully are supposed to be able to keep part of the resulting profit for bonuses and investment under their control. Prices have also been deregulated gradually and are now mostly free of controls for output not subject to mandatory planning, although subsidies and production quotas in agriculture still keep down grain prices.

Price ceilings for consumer goods historically were supported by formal rationing of some staple foodstuffs and other daily necessities as well as of a number of consumer durables. However, this system has been virtually replaced by market allocation, together with far higher prices, although housing may still be purchased through work units at a much lower price.

In recent years a dual market for urban housing has developed. Some apartments of relatively high quality are leased through the market at some of the world’s highest rents. For example, Shanghai has rents much higher than those in New York City and nearly as high as those in Tokyo.

**LARGE-SCALE INDUSTRIAL REFORM**

Although larger-scale industry has remained subject to central planning controls, similar market-type reforms have long been implemented as reformers have expanded market links within the state-planning network while reducing control by government agencies. The number of ministries and commissions directly under the State Council was cut in 1982 from ninety-eight to fifty-two and subsequently to forty-one, and their total staff was cut from 49,000 to 32,000. As their decision-making rights grow, enterprises are supposed to become more profit oriented in order to be stimulated to reduce waste, raise quality and labor productivity, upgrade production, and better tailor their products to user needs. They are supposed to move away from the one-sided emphasis on output volume—a hallmark of the command economy. In addition, provincial governments and more than nine hundred enterprises now have the right to conduct foreign trade on their own.

The economy by the late 1980s had become overheated with increasing rates of inflation. The economy regained momentum during the early 1990s after Deng Xiaoping’s Chinese New Year’s visit to southern China in 1992 gave economic reforms new impetus. The Fourteenth Party Congress later in that year confirmed Deng’s renewed push for market reforms, declaring that China’s key task in the 1990s was to establish a “socialist market economy,” an economy that would accommodate a variety of forms of ownership and permit coexistence of government planning and market mechanisms. Continuity in the political
system but bolder reforms in the economic system were proclaimed as the hallmarks of the ten-year development plan for the 1990s.

**Twenty-First-Century Challenges**

In spite of China’s impressive economic growth during the past two decades, reforming the state-enterprises sector, creating a social-welfare system, and modernizing the banking system remain major hurdles. Many small, unprofitable enterprises have been closed or sold, but larger money-losing enterprises are usually merged with viable state enterprises or simply continue to be subsidized. Most workers who have been discharged have continued to receive minimum compensation, including early retirement and opportunities to go into business for themselves.

China has three types of economic activities: those that are stipulated by mandatory planning, those that are done according to indicative planning (in which central planning of economic outcomes is indirectly implemented), and those that are governed by market forces. The second and third types have grown at the expense of the first type, but goods of national importance and almost all large-scale construction come under the mandatory planning system. Operational supervision over economic projects has devolved primarily to governments at the provincial, municipal, and county levels. The market economy generally involves small-scale or highly perishable items that circulate only within local market areas. In addition, enterprises themselves are gaining more independence in a range of activities. Almost every year brings changes in the lists of goods that fall under each of the three types of planning. The Chinese economic system overall contains a complex mixture of relationships: state ownership, shareholding, private ownership, collective ownership, foreign direct investment, and public ownership through shareholding. Indeed, the nonstate investment in fixed assets in China at the beginning of the twenty-first century reached 47 percent of its total and has continued to grow. China continues to search for an optimal balance between plan and market, although the Communist Party reserves the right to make broad decisions on economic priorities and policies.

Education System

Jiàoyù zhìdù 教育制度

China’s educational system, the largest in the world, achieved remarkable gains from 1949 to 2009, despite political upheaval and relatively low levels of funding—resulting in dramatically improved literacy rates, sky-rocketing enrollment in colleges, and the focus on developing internationally competitive universities. How China faces the next decade’s set of challenges will be the focus of educators worldwide.

When the People’s Republic of China was founded in 1949, 20 percent of school-age children attended primary school. Sixty years later enrollment is over 99 percent, and the national illiteracy rate has plummeted from 80 to below 10 percent. China’s schools serve more than 200 million primary and secondary school students, nearly 19 million college students, and well over 5 million adult higher education students. Educational quality rather than quantity now preoccupies policy makers, educators, and the public, all of whom desire education that is effective, equitable, innovative, and life-long.

During the next decade educational reform will remain challenging. Slowing economic growth, rising expectations for educational access through college, increasing unemployment among high school and college graduates, lack of accreditation and quality control systems in higher education, rapid urban-rural migration, and a persistent gap in educational quality and opportunity between rural and urban communities require urgent attention. In this context, China’s first education educational reform plan of the twenty-first century charts a twelve-year course for education aligned with the goals of social and economic development for a “harmonious, moderately prosperous society,” technology innovation, improvement of rural education and teachers’ welfare, and systemic reform of elementary, vocational, and higher education.

Achieving Universal Basic Education

China’s education system is anchored by the belief in the power of schooling. Surveys show that family budgets give top priority to educational expenses, followed by health and housing. Reforms in education through much of the 1990s brought a shift of financial responsibility from the central government to local communities. State funding of education dropped from 84.5 percent of total costs in 1991 to 64.7 percent in 2006, and tuition as a source of funding increased from 4.42 to 15.8 percent in 2006. The decrease in national funding forced schools at all levels to generate income from school businesses, services, and fee-paying students, worsening educational gaps between rich and poor counties. During the last ten years the state has recentralized some financial responsibility primarily through poverty-relief and basic education support programs. Nevertheless, school funding remains a point of controversy. Although national policy...
prescribes government expenditures of 4 percent of GDP (gross domestic product) on education, current estimates range from 2.2 to 3 percent, a figure virtually unchanged since the 1950s.

To address educational disparity between rural and urban regions in particular the state has relied primarily on school finance reform. Beginning in 1986, funding was decentralized, and county- and village-level education offices gained a greater degree of decision-making power. While elite urban schools received considerable public support, financial responsibility for rural schools was left largely to local communities that relied heavily on surcharges. The current bright spot in enhancing educational equity is the Two Exemptions and One Subsidy (TEOS) policy that provides students financial support for school fees, textbooks, and boarding costs. Along with the establishment in 2005 of the Rural Compulsory Education Assured Funding Mechanism, which has rationalized and re-centralized to the central and provincial levels universal support for rural and urban compulsory schooling, the state has finally made central to its efforts to “build a socialist new countryside” genuinely free basic education.

Since the 1980s a majority of urban children have attended preschool, reflecting the mobilization of women outside the household and China’s one-child-per-family policy. By 2006 gross preschool enrollment rates reached 39 percent for three- to five-year-olds. In 2007 China’s 320,061 primary schools enrolled 105.64 million pupils. Net enrollment rates reached 99.49 and promotion rates were 100 percent. Declining primary-school enrollments have allowed officials to close poor schools, in some cases decrease class size, and increase teaching standards. Revised standards for the primary school curriculum, instituted on a trial basis in 2001, have enabled well-rounded training in language arts, mathematics and sciences, social studies, physical education, and music and art. English-language and information-technology instruction begin in third grade in schools with sufficient resources.

Since the mid-2000s China has put in place policies, largely fiscal, that ensure free compulsory schooling. In 2007 China’s gross enrollment rate for pupils in junior secondary school (grades seven through nine), a part of the compulsory education system since 1985, was 98 percent. Coastal cities that have universalized junior secondary schooling have eliminated selective entrance examinations in favor of neighborhood schooling. Junior secondary schools enrolled approximately 57.36 million pupils nationally in 2007.

Graduation from junior secondary school represents the transition of adolescents to stratified senior secondary schools, work, or unemployment. Although junior secondary school dropout rates remain worrisome, between 1990 and 2007 promotion rates to senior secondary school increased from 40.6 to 75.7 percent. Senior secondary schooling is nearly universalized in metropolitan areas such as Shanghai, where 98 percent of junior secondary graduates continued their education in 2007. Reforms in senior secondary school have included new textbooks, elective courses, information technology, credit systems, and an approach to moral education that stresses community participation, “healthy leisure,” and discovery learning. New curricular standards established in 2001 give individual schools more flexibility in deciding how their teachers can best engage students in a well-rounded course of study in Chinese, English, mathematics, biology, chemistry, physics, computer sciences, social studies, geography, arts, music, and physical sciences. College preparatory courses, criticized by some as being too difficult, have been streamlined to offer students time for co-curricular pursuits. Systems of accreditation are being established for advanced teachers and private schools; in-service training and increased educational qualifications are required for teachers and principals.

The content, guidelines, and structure for competency and matriculation examinations are also adapting to meet changing curricular standards. Many cities and provinces have adopted a college entrance examination system that requires examinations in Chinese, English, and mathematics plus one or two optional subjects, usually chosen from history, physics, politics, and chemistry. High-achieving students sometimes are exempted from exams. Expanding college enrollment drives such reforms. The chances for students in metropolitan centers to enter college have never been greater (but college has never cost more). Living in educational centers greatly improves a student’s chance for higher education; such centers have more resources to spend on education and consequently have more desks available in high schools and colleges. Of Beijing’s senior secondary graduates, 75.9 percent entered higher education in 2008.
In spite of state efforts to make compulsory schooling accessible for all children, rural education faces significant challenges. Most recently the devastation of schools and the deaths of over 10,000 school children as a result of the 2008 Wenchuan earthquake became a lightning rod for public outcry at the lack of attention to rural schooling, in spite of improved supervision at the national level. Pressures for junior middle school students to become migrant workers explain drop-out rates that reach 30 percent or higher. Nearly 70 million children of migrant parents are “left behind” in homes with one or no parents, leaving rural schools overwhelmed with custodial responsibilities. At least until the economic downturn of 2008 as many as twenty million migrant children under 18 years of age were living in cities and working as laborers, many without access to schooling (Ministry of Education 2005; China Statistical Yearbook 2006).

Admission to senior high school is difficult for rural students who have proportionately fewer high school options than their urban counterparts. Many rural students who are successful in college preparatory high schools cannot take full advantage of the dramatic expansion of higher education, whose gross enrolment rates were 23 percent in 2007 compared to 3 percent in the early 1990s. High college tuition on top of heavy high school fees creates a financial burden beyond the means of poor rural families. Likewise, midwestern and western provinces have far fewer quotas than their eastern counterparts for entrance of their students into prestigious institutions of higher education.

Expanding Tertiary Education

Until the last ten years the base of China’s educational pyramid, relative to that of other developing countries, has been broad whereas the top has been narrow. In 1990 3 percent of Chinese eighteen- through twenty-two-year-olds were studying in tertiary institutions, compared with 8 percent in India; fewer than one out of every one hundred citizens was a college graduate. Since China’s integration into the global economy, higher education has entered a phase of unprecedented expansion. During the first decade of the twenty-first century the proportion of eighteen- through twenty-two-year-olds in higher education has increased from 9 to 23 percent.

In 2007 enrollment in 1,908 regular tertiary institutions was 18.85 million. Enrollment in adult higher education was well over 5 million. The continuous rise in the number of people pursuing bachelor and master degrees has offered an enormous market for education and training but also has lead to a mismatch between college degree holders and the labor market.

Along with expansion comes the desire to build world class schools—in mid-1990s the 211 Project, to strengthen programs and disciplines in one hundred key universities for the twenty-first century, and in the late 1990s the 985 Works, to build up several universities to an internationally advanced competitive level—and the need to prioritize state funding for the very top-ranked colleges.

Reforms in higher education have been aimed at decentralized and/or diversifying funding and increasing institutional accountability and quality. While even elite institutions have grown substantially, primarily due to consolidation, second and third tier institutions have increased dramatically in number and size. Majors and disciplines are being redefined. Some colleges allow qualified students to graduate early. At the same time benefits such as housing, education, and health services for college staff and faculty have decreased as colleges contract out services. Whereas the number of college students grew from 2,184,000 in 1992 to 18,850,000 in 2007 the number of support staff grew much more slowly from 1 million to just under 2 million.

Financial aid and student services stand at the forefront of change. Measures at the national, provincial, city, and institutional levels to help students afford college have accompanied striking increases in tuition, which in Beijing in 2007 ranged from 5,000 yuan for ordinary majors at second-tier institutions to 10,000 yuan for performing arts and arts design courses at elite institutions. Colleges that offer teaching and research assistantships, the banking industry, and the Ministries of Education and Finance support national student loan programs. Questions of equity remain. First, a sound system of financial aid is still underdeveloped. Since 1997, Chinese higher education funding has been increasingly tuition-driven and expensive. Meanwhile, accompanying the increasing gap between the rich and the poor and the massification of higher education, families from more diverse socio-economic backgrounds have become involved in higher
education (Ding, 2006). According to official statistics, there are now 2,400,000 impoverished college students in China, accounting for 20 percent of the undergraduate population. Furthermore, these students from lower-income families are more inclined to choose normal or agriculture universities, which provide free education or education at low rates of tuition. First-tier universities are inclined to accept students from wealthier families, while second tier universities are inclined to accept more poor students (Ding, 2006). How to provide enough need-based financial aid to achieve equality in access to higher education has emerged as a huge educational problem in China. In addition, students from the hinterland have much less chances

Raising Teaching Standards

Efforts have been underway for well over a decade to require teachers in primary and secondary schools to have four-year college degrees. A national continuing education mandate requires in-service training of 240 to 520 hours every five years. Such efforts to raise standards, coupled with expansion in secondary and tertiary education, have created a shortage of qualified teachers. The teacher-student ratio in colleges increased sharply; at the same time a record number of faculty members was on the verge of retirement, up from 5.6 percent in 1992 to 15.5 percent in 2004. Colleges now are compelled to attract teachers by increasing salaries and opportunities for foreign travel. Competition has also developed among colleges in the training of teachers. Comprehensive colleges are encouraged to institute teacher-training programs, and normal colleges are responding with more specialized and flexible training options.

Improving the stability and quality of the teaching force is critical in rural areas where primary school teachers until recently were not state employees but instead were hired by local communities as minban (community managed) teachers. Minban teachers work in public and community schools but are paid by subsidies and non-budgetary allocations from villages. Because such teachers do not receive a regular salary from the government, they have difficulty maintaining an adequate standard of living. In response, several ministries recognized qualified minban teachers as state employees. In impoverished counties in rural and western China regional variations in the quality of the teaching force have also inspired distance education programs for female and ethnic minority teachers.

In the sixty years after the founding of the People’s Republic of China the national illiteracy rate has plummeted from 80 percent to below 10 percent. PHOTO BY JOAN LEBOLD COHEN.
Private Schools Filling the Gap in Capacity

Private schooling reemerged at all levels of the education system during the 1990s. In 2007 more than 95,000 non-state educational institutions existed, reflecting a diversity of programs and administrative and fiscal autonomy. Non-state preschools and kindergartens accounted for 60 percent of the total. In addition, China had more than 16,000 non-state primary and secondary schools, 297 nationally accredited non-state colleges, and 318 independent colleges affiliated with state universities, and more than 900 pilot non-state colleges offering diploma courses.

Among the reasons for the increase in private schools have been lack of state funding, rigidity in the public sector, and restricted entrance to public schools. The state’s policy of encouraging, guiding, and effectively administering private schools was also intended to boost the economy by prompting families to use their savings on the one “commodity” they desire—education for their children.

As private education has become a major force in reform, many private schools are short-term or proprietary institutions. Others provide a forum for experimentation in teaching and community-government relations. For example, private girls’ schools experiment with an array of curricula—in music, drawing, martial arts, driver’s training, information technology, and psychology—that is designed to meet the needs of healthy female development. Such schools fill educational gaps left by a state that has not been able or willing to provide sufficient schooling to meet public demand. Because private schools face opposition from local authorities who are protective of scarce funds, many such schools are enmeshed in community-level conflicts. As state schools or branch schools run by public institutions have expanded, many private schools have also been forced out of business.
Educating the Margins

Inequalities in access to a good education in China are a result of complex patterns of historical regional, ethnic, and gender discrimination. Primarily, China’s best-educated and worst-educated regions reflect the economic disparities between the coastal and interior regions.

China has been a high-profile participant in international efforts to eliminate illiteracy and exploitative child labor and to universalize basic schooling. Outside aid from organizations such as the United Nations and World Bank and domestic support from programs such as Project Hope, the China Youth Development Foundation’s social welfare program, have focused on these goals, especially in areas where the poorest 20 percent of China’s population live. Efforts in the 1990s and 2000s have primarily been directed at the two-thirds of illiterates and school dropouts who were poor, minority, rural females.

China has reintroduced all-girls’ schools and classrooms in both rural and urban communities.

As noted above, female students comprise an increasing proportion of the enrollment of non-compulsory schools. However, their location within the system (disproportionately weighted in the humanities, foreign languages, and teacher education) is still largely determined by gender. As of 2006 nationwide, 48.06 percent of students in regular higher education institutions were female. Female full-time teachers made up 44.42 percent of college teaching staff, 45.64 and 54.79 percent of the general secondary and primary staff, respectively, and 92.72 percent of kindergarten staff. Females made up 50.38 percent of students in senior vocational high schools, 46.83 percent in senior high, and around 45 percent in regular and vocational junior high schools.

China’s campaign to universalize basic education has also shined a spotlight on ethnic minority regions, which span 60 percent of China’s territory and lag behind in education and economic indicators. Although minority students usually attend primary schools at Han Chinese levels, literacy rates for twenty-eight of the fifty-five minority groups are below that of the Han majority; minority students are considerably underrepresented in secondary and higher education. A system of two-track schools that teaches in either Mandarin or the local minority language perpetuates discrimination. The system, designed to protect minority cultures, places minority students at a disadvantage in competing for jobs in business and government, which require Chinese-language skills.

China’s disabled population arguably is the group that is most marginalized by the practices of formal and non-formal education. The government in 1990 enacted legislation to protect the rights of China’s 60 million disabled citizens, 25 percent of whom live in poverty. That same year the Ministry of Education signed the Special Education Project Task Agreement with twenty-one provinces to universalize compulsory education among disabled children. At that time 358,372 disabled children were enrolled in all types of schools, almost exclusively outside mainstream education. The numbers had increased slightly to 374,500 by 2002. Special education provision remains hampered by China’s lack of qualified special educators and facilities.

Education and Globalization

China’s eleventh five year plan, 2006–2010, has shifted the nation’s overall priorities from rapid growth and the creation of wealth to “common prosperity” and sustainable social and economic development for the creation of a harmonious society. The educational system is linked to this cause through policies designed to increase educational opportunity and excellence. All schools are to offer accessible, high-quality, student-centered education, and a top tier are to become world class institutions promoting scientific innovation and creativity. These “world-class” aspirants are part of a global educational culture, exchanging students, teachers, and knowledge with counterparts around the world.

How China deals with the challenges of its education system matters well beyond its national boundaries. Teachers and scholars worldwide look to China’s education system for inspiration. Students who are emerging from China’s schools are shaping global patterns of the production of knowledge, particularly in science and technology. Lastly, collaborative scholarly networks, improved as more Chinese intellectuals participate in international scholarly and professional organizations, have resulted in an explosion of research on Chinese education. These trends suggest that China will be a leader in educational reform in the twenty-first century.

Heidi A. ROSS
The Girls “Left Behind”

I was born into a poor farming family. I have several sisters, and parents aged and weakened by years of hard work. Three years ago we had a most unfortunate surprise. Father’s liver had hardened to an advanced stage. This added substantially to the family’s burden. Mother bravely hid her constant tears, but we knew things needed to change. Older sister quit school to earn money to help pay for father’s treatments. To lessen the financial strains on the family, I also left school to help out at home. The instant I stepped out of the schoolyard for what I thought was forever, tears streamed down my face. (A left-behind girl, fourteen years old).

Further Reading

Adult education in China evolved from simply eliminating illiteracy (between the 1950s and 1970s) to serving the public as an alternative to the conventional school education (since the 1980s). Student populations grew to include others besides workers and peasants, while the types of programs and subjects increased to serve the needs of the general population wanting to expand the breadth of their knowledge.

When the People's Republic of China was founded in 1949, about 80 percent of its population was illiterate. The immediate task of the new government in need of a skilled labor force was to provide literacy education. The Council of Government Affairs (now the State Council) issued an executive order that specified that the top priority in education was to eliminate illiteracy among workers and peasants. The order called on the public to launch a literacy movement nationwide in an attempt to gradually decrease illiteracy. This wave of literacy education shaped adult education in China.

Adult education was first labeled as worker-peasant education or after-work education between the 1950s and 1970s. The designation adult education came about in the early 1980s with the development of economic reform, an increase in the need for learning, a wider audience receptive to education, and the enrichment of this type of education in format and content. The central government issued the Development Outline of Education Reform in China (1993), which specified that adult education would serve the public as an alternative to the conventional school education.

**Student Populations**

China's adult education provides educational opportunities mainly to the following:

- Illiterates who need basic reading and writing skills
- Employed workers who need training to advance their skills or to transfer to a different position
- Job seekers who need training to meet the requirements of knowledge and skills in the professions in which they seek employment
- School dropouts who want to complete their secondary or college education and earn diplomas or degrees
- College graduates and professionals who want to update and advance their knowledge and skills in their professions
- Members of the general public who want to learn about topics such as health, finance, law, and family planning, or want to enrich their lives with various hobbies
Instructional Models

Adult education in China can be roughly divided into four categories:

- Adult primary education for workers and peasants, or literacy classes that offer basic reading and writing skills.
- Adult secondary education, which also includes training in vocational, agricultural, and technical programs, courses taught by radio and closed-circuit television broadcasts, and tutoring for individuals who want to pass an examination to earn a diploma or certificate through self-study.
- Adult higher education, which includes university-level courses taught by radio and closed-circuit television broadcasts, administrative cadres institutes, teacher-education colleges, and distance-learning colleges.
- General distance learning using online or correspondence courses.

All these categories of adult education are under the authority of the Department of Adult Education and Vocational Education at China's Ministry of Education. Offices implementing adult education are under the education authorities in provinces, autonomous regions, municipalities and prefectures, counties, or townships.

The industries involved in adult education range from mechanics, electronics, civil engineering, environmental protection, chemical engineering, light industry, coal, and metallurgy to railway, transportation, agriculture, and forestry. The public organizations involved in implementing adult education include democratic parties, public organizations, academic organizations, trade unions, and Communist Youth League offices at different levels; independent enterprises and individuals often advocate for adult education programs as well. Another important partner of the Ministry of Education in adult education is the Chinese Association for Adult Education. Founded in 1981, it is a social organization for all members of participating in adult education in China. Its main functions are to publicize, organize, and coordinate the activities of adult education; provide consultation and training; and carry out international exchange relating to adult education affairs.

Adult education can be pursued full-time or part-time in the classroom, by taking online courses, and through individual tutoring. The curricula have expanded to include liberal arts, natural sciences, engineering, medical science, agriculture, finance, political science and law, education, and sports. The programs can result in a diploma, a degree, or a certificate or be simply for pleasure and personal enrichment. Most diploma or degree programs can be completed in two or three years. A few offer a four-year regular undergraduate curriculum.

Further Development

Strategies to develop or improve adult education in China focus on job training, continuing education, and community education. One focus is to establish an adult education network among counties, townships, and villages in the countryside to help promote education in literacy, applied technology, democracy and legal systems, environmental protection, family planning, and other areas. Another priority is to encourage corporate sponsorship systems, vocational certificate and licensure systems, and other flexible approaches to adult education. It is also important that laid-off workers and workers needing job transfers will have opportunities to receive vocational training or formal education at different levels and be prepared for re-employment, and that improvements are made to the examination system for those pursuing self-study. Establishing a network of adult education that is accessible to the whole society will certainly impact China’s future for the better, as will initiating experimentation in community education and fostering the concept of lifetime education.

Further Reading

Beginning with the leadership of Deng Xiaoping in 1978, and in the thirty years since, China has put forth great efforts to provide compulsory, free and universal education to children from grades one through nine cross the nation.

After Deng Xiaoping resumed his political career for the third time in 1978, one of his first acts as China’s paramount leader was to redirect the nation’s focus toward economic development. Deng recognized that it was important to raise the population’s education level if China were to realize the Four Modernizations 四个现代化 in agriculture, industry, technology, and defense.

In 1984 authorities began to formulate major laws affecting education. One notable idea of 1985 was to provide nine years of compulsory education. On 1 July 1986, the Compulsory Education Law of the People’s Republic of China 中华人民共和国九年义务教育法 was enacted. The law provides three components: compulsory, free, and universal education. Compulsory means an obligation of the school, parents, and society to guarantee all school-age children the right to receive nine years of basic education. Free refers to no charge for tuition and miscellaneous fees to pupils. Universal indicates setting standards for textbooks, curricula, financial management, and construction. The administrative model had the central government overseeing, local governments executing, and a multilevel government structure managing education.

Illustration of a nineteenth-century school. Deng Xiaoping recognized the importance of raising the population’s education level so that China could realize the “Four Modernizations” in agriculture, industry, technology, and defense.
The funding structure was pyramid-like. Lower-level governments—that is, towns, villages, and counties—shouldered most of the costs of basic education.

In 2004 the Economy Research Office at the Party School of the Central Committee of the Communist Party of China conducted a study to evaluate the implementation of the 1986 law in sixteen provinces in rural China. The findings were disappointing. The government’s so-called basically popularized compulsory education impacted only 85 percent of the country. The remaining 15 percent—mainly the impoverished regions—was far from achieving the goal of compulsory education. Even in the areas that did meet the goal, the outcomes and quality of compulsory education were tenuous, evidenced by a comeback of high dropout rates and a lack of instructional instruments and qualified teachers. The officially published dropout rate was about 5 percent, with some areas reaching 10 percent. Findings from the field investigation, however, revealed a rate of 20 percent or higher. Factors such as poverty, transportation, teacher quality, funding resources, and the public’s understanding of educational benefits all contributed to the failure of implementation.

Given this reality, the Standing Committee of the National People’s Congress adopted at its twenty-second plenum session an amendment to the Compulsory Education Law, which went into effect on 1 September 2006. The amendment generated the following improvements:

- further assurances of compulsory, free, and universal education
- a new funding structure that guarantees funding propositions at different government levels,
with the central government shouldering the major burden of funding

- clear specifications of the administrative infrastructure in which both the central and local governments jointly share the management responsibilities of compulsory education

- various strategies to ensure equal opportunity to receive an education for all school-age children and children with disabilities

- further enforcement of efforts to promote quality-based education

- a written social status and compensation structure for primary and secondary school teachers

- an emphasis on no key schools or key classes and the prohibition of changing the nature of public schools by any government above the county level and its education department

Starting on 1 September 2008, all the Chinese students within the compulsory education grades in the cities began to receive their schooling free of charge. Fees and tuitions for the students of the same group in the country had been eliminated since 2007. This means that China has now realized its goal of free education to all students of the compulsory education grades.

Further Reading

China is making strides in providing education for special-needs students who have communicative, sensory, and physical disabilities, but a shortage of special-education teachers poses a challenge China’s educational system must face. Although the needs of children with other types of impairments are beginning to be addressed, China has yet to pay much attention to some other special-needs students, such as the gifted and talented.

Special education in China historically refers to education for children with disabilities—mainly, with communicative, sensory, and physical impairments. With the development of special-education theories and practice, the field of special education has expanded to include education for children with developmental, psychological, mental, cognitive, and social impairments. Other special-needs children, such as the gifted and talented, have yet to receive more attention in China.

History through 1987

Formal special education was first introduced into China by Western missionaries and charitable organizations around the 1870s and was limited to children with hearing, seeing, and speaking impairments. The missionaries to China brought Braille and sign language; later they developed the first generation of the reading system of Chinese characters. This generation of Braille had more than one version to accommodate different dialects in southern regions, especially Fujian dialect, Cantonese, and Nanjing dialect. In addition, this Braille system was limited to areas other than northeastern regions and was in use until the publication of the second generation in 1953. The curricula during that time focused on basic academic knowledge, living skills, and religion.

The first schools of special education run by the Chinese were not founded until the early twentieth century, initially by philanthropists and charitable organizations and later by the government. The curricula included academic knowledge and vocational skills from elementary level to senior high school level. Some students with disabilities pursued college education after graduation from high school. The disabled populations served by the Chinese during that era were mostly the blind and deaf. By the founding of the People’s Republic of China (PRC) in 1949, there were about forty special-education schools that served about 2,380 blind or deaf students.

From 1949 to 1965 special education developed gradually but steadily. During this period the central government developed and executed a series of laws, regulations, and policies related to special education. To implement these law, regulations, and policies, the government allotted funds; enrolled students with sensory, communicative, developmental, and mental impairments into special schools; and arranged for graduates to work in “welfare factories” (fu li gong chang 福利工厂), or the factories designated specifically for disabled populations.
Then special education was interrupted by the Cultural Revolution (1966–1976) for more than ten years. Despite the earlier efforts, by 1984 less than 2 percent of all eligible children nationwide went through this progression, and most of that number were children in the cities, while the majority of children with disabilities were left as each family’s responsibility. Special education remained a low priority on the government agenda until China launched its economic reforms in the early 1980s.

The National Conference on Education held in 1985 started recognizing the importance of special education, and the Compulsory Education Law (yi wu jiao yu fa 义务教育法), enacted in 1986, formally called for equal education rights for children with disabilities or special needs. Partially due to this law and partially due to the high costs of special-education schools and to the promotional efforts of the China Disabled Persons’ Federation (CDPF), change set in. A nonprofit organization headed by the son of Deng Xiaoping, Deng Pufang (disabled himself due to violence he experienced during the Cultural Revolution), began taking shape to accommodate disabled children in schools. Depending on the resources available, students might study in special-education schools, in special-education classes in regular schools (fu she te jiao ban 附设特教班), or in regular classes in regular schools (sui ban jiu du 随班就读). Given the scarcity of special-education resources—notably, qualified special-education teachers and facilities—most children with disabilities or special needs had to attend regular classrooms at general public schools.

According to the First China National Sample Survey on Disability in 1987, China had a population of 51.64 million individuals with disabilities, about 5 percent of the population at that time. Of this number, children under eighteen accounted for 10.74 million, and those between six and fourteen numbered about 6.25 million.

More Recent Statistics

The Second China National Sample Survey on Disability was conducted in the spring of 2006; the preliminary results estimated that the population of people with disabilities had increased to 82.96 million, which was 6.3 percent of the total population, based on the 2005 year-end statistics (1,309.48 million). Out of this number, 12.33 million (15 percent) have a visual disability, 20.04 million (24.2 percent) have a hearing disability, 1.3 million (1.53 percent) have a speaking disability, 24.12 million (29.1 percent) have a physical disability, 5.54 million (6.7 percent) have mental retardation, 6.14 million (7.4 percent) have mental disability, and 13.52 million (16.3 percent) have multiple disabilities.

With the implementation of the Compulsory Education Law, the Protective Act of the Disabled (can ji ren zhang fa 残疾人保障法), and the Regulations for Education of the Disabled (can ji ren jiao yu tiao li 残疾人教育条例), the enrollment of children with seeing, hearing, and mental impairments increased from less than 6 percent in 1987 to 77.2 percent in 2000. In addition, 4,567 special classes were established in regular schools, and three special colleges were founded during this period. Furthermore, according to a U.N. Economic and Social Commission report, more than 2.51 million individuals with disabilities had received vocational training by 2003. According to the 2002 statistics of the China Ministry of Education, there were 1,540 registered special-education schools that together employed 40,400 teachers and other staff, with 29,800 of them working full time in the schools. In the same year, about 374,500 students enrolled in these schools, and 44,200 students graduated from their programs. But it was reported that in 2003 about 323,000 school-aged children with disabilities still lacked access to education (China Statistics Press, 2004). Statistics from China’s Ministry of Education show that, by 2006, 362,946 students with disabilities, in grade 1 to grade 10, were enrolled in 1,605 schools of various kinds. Of the 1,605 schools, 672 are in the cities, 857 are in county or town seats, and the remaining 76 are scattered around rural areas. (See table 1.)

A shortage of special-education teachers has been a pressing issue for many years in China. By 2006 there were 33,396 full-time special-education teachers, with 72 percent female and less than 6 percent minority. By 2006 there were twenty-two universities and colleges in the nation (including schools in Hong Kong) that offered four-year or advanced degrees in teaching or administering special-education programs. But the number of graduates from these schools is far from meeting the demand for special-education teachers in the whole country.
Of the special-education teachers in these schools 78 percent hold an associate or higher degree, and 21 percent hold a high school diploma. The remaining less than 1 percent do not have a high school diploma. Regarding grade placement, 48 percent qualify to teach grades 4–6, and about 36 percent grade 1. Less than 4 percent qualify for teaching senior-high grades, and 6 percent do not have a teaching-grade qualification. As for facilities in the special-education schools, by 2006 the total floor space was 4,222,436 square meters, out of which 1,797,910 square meters were allotted to instruction and related services and 489,883 square meters were for administration and teacher offices.

Eight Revolutionary Model Dramas

巴歌《革命样板戏》

The eight revolutionary model dramas, consisting of five Beijing Operas, two ballet dance dramas, and one symphonic work, were composed during the Cultural Revolution (1966–1976). Under the supervision of Mao Zedong’s wife Jiang Qing, these eight pieces were transformed into a vehicle for propagating Maoist ideology.

Traditional Beijing Opera, since it began in the late eighteenth century, evolved naturally, its development little affected by political changes. However, this state of affairs was not to last. Although some people called for its reform during the May Fourth Movement (an intellectual movement that swept through China between 1915 and 1923), only after the founding of the People’s Republic of China in 1949 did this artistic genre undergo the most radical transformation in its history. This transformation came about because Chinese Communist Party (CCP) leader Mao Zedong (1893–1976) wanted literature and art to serve political goals. Beijing Opera was not fit to perform this function with its age-old stage conventions and its repertoire of stories about ancient emperors and generals, scholars and beautiful ladies. During the Cultural Revolution Jiang Qing seized this opportunity to remake Beijing Opera to serve a political purpose. The results were the so-called eight revolutionary model dramas (革命样板戏).

Synopses

The eight model dramas consist of the following pieces:

(1) On the Docks (Hai gang) portrays a group of dockworkers rushing to load grain bound for Africa before an approaching typhoon. The good workers, armed with Mao Zedong’s thought and the proletarian internationalist spirit, expose a dispatcher’s sabotage. (2) Raid on the White Tiger Regiment (Qixi Baihu Tuan 奇袭白虎团) depicts how a unit of the Chinese People’s Volunteers wipes out a South Korean regiment and captures its U.S. advisors during the Korean War. (3) Shajiabang 沙家浜 was adapted from the Shanghai Opera Sparks amid the Reeds (Ludang huozhong 芦塘火种). It describes how the soldiers of the New Fourth Army smash the encirclement campaigns of the Japanese invaders and their Chinese puppets with the help of a clever teahouse proprietor, who is an underground Communist Party member. (4) Taking Tiger Mountain by Strategy (Zhiqu Weihushan 贼取威虎山) was based on Qu Bo’s well-known novel, An Ocean of Forest and a Plain of Snow (Linhai xueyuan 林海雪原). This opera depicts a battle during the Chinese civil war in which the Communist forces wipe out a bandit chieftain and Guomindang 国民党 (Chinese Nationalist Party) brigadier in his mountain stronghold in northeast China. In (5) The Red Lantern (Hongdeng jī 红灯记) a railroad worker tries to deliver a secret code to the Communist guerrillas in the mountains. He and his mother are arrested by the Japanese police and executed, but his daughter succeeds in delivering the code. The red lantern is used as a signal...
by the Communist underground and is also a symbol of revolutionary spirit. (6) Set on Hainan Island 海南岛 in the 1930s, the ballet Red Detachment of Women (Hongse niangzijun 红色娘子军) dramatizes how a group of peasant women defeat a local despot and joins the Communist army. (7) The ballet The White-Haired Girl (Bamao nu 白毛女) was adapted from a well-known opera of the same name with lyrics by the poet He Jingzhi 贺敬之. He based his opera on a folk story about a peasant girl who flees from an evil landlord to a mountain and after living in a cave for several years has her hair turn white. She is finally rescued by the Eighth Route Army that liberated her village. (8) The symphonic work included in the group is also called Shajiabang.

Themes and Theories

As can be seen from the synopses, most of these model dramas deal with wars (the War of Resistance Against Japan, the Chinese civil war, the Korean War). Closely related to the war theme is the theme of class struggle between oppressive landlords and poor peasants. To enact past wars and struggles is to spur the Chinese people to continue revolution in the present. In On the Docks (1963), the only opera not set in wartime, class struggle is broadened into a global power struggle between East and West in which China supports Third World countries in their struggles against imperialists. The dispatcher, who tries to prevent a shipment of seed rice to Africa, is an agent of the imperialists, who do not want the African people to become self-sufficient in food supplies. Another characteristic of the model dramas is the prominence of women characters, who are portrayed as loyal and capable party members (Sister A-qing 阿庆嫂 in Shajiabang, Fang Haizhen 方海珍 in On the Docks) or as oppressed peasants transformed into revolutionary warriors (Xi’er 喜儿 in The White-Haired Girl, Wu Qinghua 吴清华 in Red Detachment of Women). However, women’s gains in social status are achieved at the loss of their feminine attributes. These women characters have no husband, no family, and no intimate relationships. The budding love between Xi’er and the PLA soldier who rescued her, the affection between Wu Qinghua and a leader of the militia, and the love affair between a regimental chief of staff and an army nurse (Taking Tiger Mountain by Strategy) in the original sources were all eliminated in the adaptations to emphasize class struggle and revolution. In the model dramas there is no room for love except love for the Communist Party and Chairman Mao. The traditional Chinese family is also conspicuously absent. The only family that appears in these works is the surrogate family in The Red Lantern. The three members of the railroad worker LI Yuhe’s 李玉和 family (Li and his adopted mother and daughter) are not related by blood ties but rather by their shared belief in the Communist revolution. Likewise, Sister A-Qing and the eighteen wounded soldiers from the New Fourth Army form a revolutionary family. Even grandmothers (Grandma Li in The Red Lantern, Auntie Sha in Shajiabang, the Korean woman Auntie Choe in Raid on the White Tiger Regiment) actively support the revolution.

The content and composition of the model dramas were guided by Mao Zedong’s “Talks at the Yan’an Forum on Literature and Art” (1942), which Jiang Qing claimed to be her source of authority. To implement Mao’s guidelines, she formed a “tri-unification” (san jie he 三结合) work team: party leadership, professional personnel, and the masses. As a representative of the party, she set the themes and guided the selection and revision of the texts for use. A team of playwrights, composers, and performers then produced the operas and ballets, which presumably reflected the revolutionary experiences of the masses (workers, peasants, and soldiers). The masses were invited to offer their opinions for any revisions, but the final decision rested with the party leadership. In addition to this tripartite production team, the principle of “three prominences” (san tuchu 三突出) was adopted and resulted in this formula: Give prominence to positive characters, heroic characters, and the main heroic character, in ascending order. As a result of this principle, the main heroes appear as superhumans without any blemishes. On the opposite spectrum the negative characters are all stupid, cowardly, and ugly. Both the heroes and villains are cardboard figures without any depth. This kind of stereotypical characterization conformed to another ideal of Mao, that is, revolutionary realism and revolutionary romanticism. This ideal means that literature and art should not passively reflect reality but rather should actively impel reality forward.
and transform it. In other words, the characters in the model dramas are not found in real life; they are found only in theory and concepts. Another slogan that was applied to the production of these dramas was “Make the ancient serve the present, the foreign serve the Chinese.” Jiang Qing’s model works employed an old art form (the Beijing Opera) and Western art forms (ballet and symphony) to launch the Cultural Revolution.

**Impact and Influence**

During the Cultural Revolution model dramas dominated the Chinese stage because all other forms of performance were banned and actors of the old school persecuted. The saying “eight model dramas for 800 million people” aptly described the cultural situation at the time. Not only Beijing Opera troupes were required to perform these operas; regional theater troupes throughout the country also were required to do the same. Minority peoples’ theaters were no exception, either. For example, in the Xinjiang Uygur Autonomous Region, Uygur actors translated Red Lantern into their language and set their traditional music to it. As the power of the original eight model dramas reached a peak, several revolutionary operas were created in the early 1970s, such as Azalea Mountain (Dujuanshan 杜鹃山), Song of the Dragon River (Longjiang song 龙江颂), and Fighting in the Plain (Pingyuan zuozhan 平原作战). However, the fortune of the model dramas changed with the end of the Cultural Revolution; their decline came as quickly as their ascendance. The new party leadership declared the Cultural Revolution a national disaster and distanced itself from anything that evoked the memory of that period. In recent years, as the Cultural
Revolution has receded into history, the model dramas have become popular again, and some of them have been restaged. This renewed interest reflects the Chinese people’s desire to preserve these dramas as a part of their cultural memory, now that they can enjoy them from a safe distance. The experiments of the model dramas, minus the political propaganda, can also be useful in producing new operas on contemporary themes in order to make the old drama more relevant to contemporary audiences.

Eight-Legged Essay

Bāgūwén 八股文

Starting during the Ming dynasty (1368–1644) and continuing for hundreds of years, the “Eight-Legged Essay” was the required eight-part response to civil service examination questions based on Confucian thought. The extremely formulaic essay, which had both critics and defenders over the years, evolved as a way for official examiners to impartially evaluate the work of tens of thousands of candidates.

Most accounts of the development of the late imperial examination essay begin with modernist apologies. The twentieth-century cultural assault on the infamous Eight-Legged Essay (bagu wen)—as the classical essay on the Confucian texts, the Four Books and Five Classics, was called since the fifteenth century—has included accusations that the essay became a byword for petrifaction in Chinese literature or that the essay itself was one of the reasons for China’s cultural stagnation and economic backwardness in the nineteenth century.

Origins of the Eight-Legged Essay “Grid”

Whatever the literary verdict, the late imperial examination essay had its most immediate roots conceptually in the epochal transition from medieval belles-lettres (literature that is an end in itself and not merely informative) to the classical essay (jingyi) championed by Wang Anshi (1021–1086) in the eleventh century. The classical essay, however, was not firmly in place empire-wide in civil examinations as the key literary form until the early Ming dynasty (1368–1644). When the Eight-Legged Essay was still the rage, before 1850, many efforts were made to trace a history of ideas about its literary pedigree. In fact, when it was still fashionable to do so, champions of both parallel-prose and ancient-style prose essays each claimed the Eight-Legged Essay as a kindred genre to legitimate their competing literary traditions in the late nineteenth and early twentieth centuries. The eight “legs” (ku, bones) of the classical essay referred to the parallel and balanced lines that made up its structure.

The examination essay style that was specifically called the “Eight-Legged” style appeared for the first time in the early years of the Chenghua reign, 1465–1487. Consequently, the tendency to construct the historical genealogy of the Eight-Legged Essay from the earlier dynasties tends to elide its sudden appearance in the 1480s as the accepted form for an examination essay. Later claims that the form derived from earlier styles served to legitimate the Eight-Legged Essay as the harvest of past literature and classical learning. As in earlier such cases the literati themselves, not the imperial court, initially produced this new trend in classical writing.

Although detractors of the Eight-Legged Essay genre have received a more sympathetic hearing in the twentieth century, its late imperial advocates were numerous and came from a broad spectrum of literati. Li Zhi (1527–1602), a late Ming iconoclast on so many issues, saw in
the evolution of classical essay genres a cultural dynamic that was commentary to the ongoing literati search for values in antiquity. The Eight-Legged Essay represented a “contemporary-style essay” for Li and was a genuine genre that had proven its worth by producing famous officials. Their moral achievements, he thought, were because of the use of an orthodox genre for the classical essay in civil examinations.

The Hanlin academician Liang Zhangju's (1775–1849) early nineteenth-century work entitled Zhiyi conghua (Collected Comments on the Crafting of Eight-Legged Civil Examination Essays), while mentioning the accruing flaws in the selection process, praised the artistic and cultural levels that the examination essays fostered in Chinese life. Liang noted that no one to date had come up with an acceptable alternative. Qing dynasty (1644–1912) literati who prepared prefaces for the work, which was designed to place the examination essay in full cultural relief, wrote in praise of their dynasty's contributions to the further evolution of the Ming genre.

In the late seventeenth century Gu Yanwu (1613–1682) dated the Eight-Legged Essay with more historical precision to the mid-fifteenth century, when essays began to appear in a clear sequence of eight parts:

1. breaking open the topic (poti),
2. receiving the topic (chengti),
3. beginning discussion (qijiang),
4. initial leg (qigu),
5. transition leg (xugu),
6. middle leg (zhonggu),
7. later leg (hougu),
8. conclusion (dajie)

One of the most renowned early composers of Eight-Legged Essays was the scholar-official Wang Ao (1450–1524), who passed the 1474 Nanjing provincial examination ranked number one out of 2,300 candidates and 135 graduates. Wang then passed the 1477 metropolitan examination in Beijing, also ranking number one. In the palace examination, however, Wang Ao had the misfortune of having as his chief reader Shang Lu (1414–1486), who was at that point the only Ming literatus who had achieved “three firsts” (sanyuan) on the Ming civil examinations. He made sure that Wang would not be the second by ranking Wang’s final policy answer third overall after other readers had initially ranked it first. Shang Lu could identify Wang Ao’s paper because the palace examination, unlike the provincial and metropolitan examinations, was not graded anonymously.

Despite this downclassing, Wang Ao’s classical essays won the day outside the examination compound and beyond the reach of the imperial court. Although official rankings could be tampered with by jealous men such as Shang Lu, the latter’s writings never measured up to Wang Ao’s in the evolution of the genre that would become the Eight-Legged Essay grid. Wang Ao served frequently as a metropolitan examiner in the late fifteenth century, during which his classical essays occasionally served as models for thousands of candidates in the compounds he supervised. Accordingly, the first glimpse we have of the early emergence of the Eight-Legged form of the classical essay, before its explicit declaration as the official examination style in 1487, can be traced to Wang Ao’s 1475 essay on a passage from the Mencius: “The Duke of Zhou subjugated the northern and southern barbarians, drove away the wild animals, and brought security to the people” (Elman 2000, 387).

Cognitive Issues in Eight-Legged Essays

Many of Wang Ao’s Eight-Legged Essays were later cited in Ming and Qing examination essay collections as models for the form. One was based on a passage in the Analects: “When the people have enough, how can the ruler alone have too little?” (Elman 2000, 389). It became perhaps Wang’s most famous essay. It dealt with the ruler’s responsibilities to provide a livelihood for his people and was copied, printed, and studied by generations of civil examination candidates.

What is immediately striking about Wang Ao’s essays is their exaggerated structural commitment to formal parallelism and thinking by analogy. Strict adherence to balanced clauses (duiju) and balanced pairs of characters (shudui) was required, but this feature becomes particularly rule-like in Wang’s framing of his arguments. As the classical essay’s length requirement increased from the five hundred characters common in late Ming times to more than seven hundred during the eighteenth century,
the basic structure of the essay remained unchanged. However, a dispute in the 1543 Shandong provincial examination over the veiled criticism of the throne in the “conclusion” of an Eight-Legged Essay led to a decline in the practice of ending the essay with rhetorical flourish.

The form of chain arguments used in such essays was built around pairs of complementary propositions, which derived their cogency from rich literary traditions that over the centuries had drawn on both the parallel-prose and ancient-style prose traditions of early and medieval China. Balanced prose presupposed that an argument should advance via pairs of complementary clauses and sections that, when formalized and disciplined by analogies, avoided an unfocused narrative. Accordingly, the Eight-Legged Essay represented an effort to confirm the vision of the sages in the Four Books and Five Classics from a “double angle of vision,” which strictly correlated with the parallel syntax of the legs of the examination essay.

In the first leg of Wang Ao’s essay on the prince’s responsibilities, mentioned earlier, the ruler’s actions were directly related to a series of positive economic consequences that would ensue if he followed the way of sagely governance. In the middle leg Wang Ao’s personal assessment was delivered within a balanced sequence that analogized the households of farmers to the prince’s treasury in the first half and compared the farmers’ fields with the prince’s vaults in the second half. The final leg presented the same conclusion in light of the prince’s ritual and culinary needs, all the while stressing the priority of the people in any equation between taxes and wealth. From these three balanced legs it therefore followed that raising taxes of itself was not the sage’s method for governance.

The first leg was almost Aristotelian in its explicit rhetorical linkage of cause (low taxes) and effect (the people’s prosperity). The second leg elaborated on the first by showing how low taxes would increase the overall wealth of the realm if it remained in the hands of the people. And the final leg clinched the argument by responding to questions of how low taxes would directly benefit the dynasty and not just the people. In this manner a conclusion that ran counterintuitively to statist discourse about the wealth and power of the dynasty, which drew on legalist (relating to strict, literal, or excessive conformity to the law or to a religious or moral code) traditions, was successfully channeled into a literati discourse built around the Chinese philosopher Confucius’s (551–479 BCE) vision of a polity pegged to the interests of the people.

Based on the specific Eight-Legged grid, examiners and tutors literally followed the number of legs and counted the number of characters in an essay based on the requirements of balanced clauses, phrases, and characters. In marked-up examination essays that have survived, scholars always find numerous small circles marking exactly the balanced and antithetical clauses in each of the legs of the essay. Examiners used a set pattern of markings to distinguish the main points. This classical grid provided examiners with a simple, impartial standard for ranking essays, which has rightly been labeled “a kind of stylistically formalized classicism” (Elman 2000, 395). The grid also included rules for presentation of the essay form on paper that necessitated proper spacing of characters from top to bottom and left to right. References to the reigning emperor, for instance, had to be highlighted by raising that column of characters higher and avoiding taboo names, while the body of the essay began at a lower level in each column. Essay drafts that survive reveal that Eight-Legged Essays were copied onto paper that was divided into columns and rows to make it easier for examiners to keep track of the parallel legs of the essay.

If a candidate could not follow these strict rules of length, balance, and complementarities, then his essay was judged inferior. One misplaced character, or one character too many or too few, in building a clause in one of the legs of the essay could result in failure. Given the tens of thousands of civil candidates in the compounds where local and provincial examinations were held, the official examiners rightly felt that with a stylized and formulaic Eight-Legged grid as a requirement, their job of reading and evaluating thousands of essays in a brief time was made easier and more impartial.

Printing and Publishing Examination Essays

Civil examination papers were first compiled in the publishing rooms inside the provincial and metropolitan examination compounds, where a host of copyists, woodblock carvers, and printers worked under the
examiners. Essays were printed out with the examiner’s comments and bound according to rank. These official collections of examination essays were based on the original, anonymous essays that the examiners actually had read. Those originals were returned to examinees who requested them after the examination. In addition, the best essay on each quotation or question in all three sessions of both provincial and metropolitan examinations was included in the official examiners’ report and sent to the court for review.

The public printing of essay collections increased during the late Ming publishing boom, when the commoditization of culture intensified. The sixteenth-century increase in private, commercial collections of examination essays can be attributed to the formalization of the Eight-Legged Essay during the last half of the fifteenth century into the official essay style. The expansion of the examination market, which during the Ming and Qing dynasties added a third tier of 1,300 local county and 140 prefectural examinations, thus dramatically increased the empire-wide pool of candidates who would be interested in such collections.

Encyclopedias and Dictionaries

Bǎikēquánshù yù zìdiǎn 百科全书与字典

The first Chinese encyclopedia, Huang lan (Book for the Emperors) was printed during the reign of the Weiwen emperor (187–226 CE). China’s first dictionary was compiled in the second century. Encyclopedic writing has played a significant role in Chinese scholarship and culture, valued as the ultimate assembly of traditional knowledge. Today China publishes both comprehensive and specialized encyclopedias and dictionaries.

In China, as elsewhere, encyclopedias are reference books that cover either all branches of human knowledge or all the knowledge of a specific branch. Dictionaries in Chinese are reference books devoted to either characters or words, and in which individual components are arranged by certain methods of indexing, marked with correct pronunciations and tones, and provided with their proper forms and meanings.

Encyclopedias

The English term encyclopedia is Greek in origin, meaning “general knowledge.” The Chinese term baike quanshu comes from Japan. Baike (a hundred subjects) refers to the extent of knowledge, whereas quanshu (all books) refers to comprehensiveness. An encyclopedia provides facts and other information. At the same time, it meets educational purposes by broadening the user’s horizon and providing him or her with a systematic way of acquiring knowledge.

Encyclopedias originated from people’s desire to generalize and classify the knowledge they had acquired. The ancient Greek scholar Aristotle developed many kinds of teaching materials that broadly encompassed the knowledge available at his time. Thus he is known in the West as the father of the encyclopedia. The Chinese book Erya (Approaching What Is Proper), appearing during the Han dynasty (206 BCE–220 CE), covers the natural and social sciences and is considered the prototype of the Chinese encyclopedia. There are various traditions suggesting a much earlier origin, and the book’s significance through early Chinese history is evident since it was included among the twelve Confucian classics during the Tang period (618–907 CE). The first Chinese encyclopedia, or leishu (a book with material taken from various sources and arranged according to subjects), was Huang lan (Book for the Emperors), edited by Liu Shao, Wang Xiang, and others during the Weiwen emperor’s reign (187–226). Unfortunately, none of the several hundred leishu produced between the third and the eighteenth centuries was an encyclopedia in the truest sense. All were compilations of books already published. In a 1966 article on the Chinese encyclopedia, Wolfgang Bauer discussed the fluid boundaries between a dictionary and an encyclopedia and explained, “A longer commentary delving into history and culture and provided with extensive quotations of sources is . . . more characteristic of the encyclopaedia.” He also wrote, “Although they may include an opinion on the subject, they
rarely contain an original opinion. As countless other works of Chinese literature the encyclopaedia was usually compiled by the ‘scissor and paste’ method and not really written.”

Western Encyclopedias Explained to Chinese Readers

Encyclopedias of ancient times, such as the ancient Greek and Roman encyclopedias intended for education, were authored by individuals who used medieval methods of classification. The thirty-seven-volume *Naturalis Historia*, written by the Roman scholar Pliny the Elder during the first century, is typical of such ancient encyclopedias. Encyclopedias of the Middle Ages, bearing the theological and religious marks of the time, were mostly compiled as textbooks for clergymen serving in monasteries during the fifth to sixteenth centuries. Most of them were still based on the medieval seven-liberal-arts classification system. The eighty-volume *Speculum majus* (*Bigger Mirror*), written by Vincent de Beauvais of France, was the epitome of encyclopedias of this period. Under the influence of the English philosopher Francis Bacon, a more scientific classification system began to be adopted by encyclopedists of the late Middle Ages and has since become the basis for the compilation of modern encyclopedias.

Encyclopedias of modern times date since the eighteenth century. The pioneer was the French philosopher Denis Diderot, who led French encyclopedists in producing the twenty-eight-volume *Encyclopédie* (*Systematic Dictionary of the Sciences, Arts, and Crafts*) from 1751 to 1772. Modern encyclopedias enlighten the reader with knowledge of modern science and technologies and arrange entries in alphabetical order, like dictionaries, for convenience. Between the eighteenth and twentieth centuries, Great Britain, Germany, United States, France, Italy, Russia, and Japan produced authoritative encyclopedias, of which the *Encyclopedia Britannica* (published in Great Reference Works about China Published Abroad

Until the China Great Encyclopedia (*Zhongguo Da Baike Quanshu* 中国大百科全书) began to appear in 1978 from Encyclopedia of China Publishing House in Beijing, the most comprehensive references on Chinese culture were published outside China. The earliest of such works was probably the *Encyclopaedia Sinica*, written by an English missionary named Samuel Couling and published in 1917. Morohashi Tetsuji’s *The Great Chinese-Japanese Dictionary* (*Dai Kan–Wa jiten 大漢和辭典*) appeared in thirteen volumes from 1955 to 1959. A wide variety of European and American reference works about Chinese history, culture, and biography appeared in the twentieth century, some of them single-volume compilations designed for students, and others—like the *Cambridge Encyclopedia of Chinese History*, published by Cambridge University Press in ten volumes—are a collection of the work of many scholars. The famous reference series *Science and Civilisation in China*, also published by Cambridge University Press, had a primary author, Joseph Needham, but some later volumes were written by other scholars.

The *Encyclopedia of China Today*, a 1980 volume, was arranged in topical chapters like a textbook, not arranged alphabetically. It was the first general resource published to help Americans get up to speed on a country that they had been cut off from for nearly thirty years. The foreword—by John Service, the most prominent of the U.S. China experts to be pursued by the McCarthy Commission—is in itself evidence of the change that was taking place in the United States after the normalization of diplomatic relations between the United States and the PRC in March 1979.

In March 2009, exactly thirty years after normalization, the first comprehensive scholarly English-language encyclopedia, the five-volume *Berkshire Encyclopedia of China* was published by Berkshire Publishing Group, a U.S. company specializing in global information that had developed the six-volume *Encyclopedia of Modern Asia* published by Charles Scribers Sons in 2002.
Britain before the fourteenth edition and subsequently in the United States) is generally considered the outstanding example.

**China’s First Modern Encyclopedia**

The *Encyclopedia of China* (or *China Great Encyclopedia, Zhongguo Da Baike Quanshu* 中国大百科全书) is the first large-scale comprehensive modern encyclopedia in the Chinese language. The compilation began in 1978. Published by the Encyclopedia of China Publishing House, the encyclopedia was issued one volume at a time, beginning in 1980 with a volume on astronomy. The final volume was completed in 1993. It comprised seventy-four volumes, with more than 80,000 entries divided into sixty-six subject categories. Within each category entries were arranged by pinyin, as are many modern Chinese dictionaries. Its second edition was published in 2008. The Encyclopedia of China Publishing House has also translated and published the *Concise Encyclopedia Britannica* (ten volumes), which was originally compiled and printed by American Encyclopedia Britannica, Inc., and the *Soviet Encyclopedia Dictionary*, originally compiled and published by the former Soviet Encyclopedia Publishing House.

**Types**

Contemporary encyclopedias come in all types to satisfy the needs of readers of different professions and educational backgrounds. The encyclopedias fall into three major types: comprehensive, specialized, and regional.

Comprehensive encyclopedias cover all the branches of knowledge and are used to access basic knowledge. In accordance with readership, they are further divided into scholarly encyclopedias, such as *Encyclopedia Britannica* and *Encyclopedia of China*; popular or secondary school encyclopedias, such as *Compton’s Encyclopedia* and *Xin shijii zhongxuesheng baike quanshu* (New Century Middle School Students’ Encyclopedia); and young adult and children’s encyclopedias, such as *Oxford Children’s Encyclopedia* and *Zhongguo ertong baike quanshu* (China’s Children Encyclopedia).

Specialized encyclopedias focus on one branch or subject of knowledge, and their coverage can be as broad as that of the U.S. *Encyclopedia of Science and Technology* or as narrow as that of the *Zhongguo jiyou baike quanshu* (Chinese Encyclopedia of Stamp Collection).

Regional encyclopedias are limited to a certain region, country, or even a city, such as the *Encyclopedia of Asia, Jianming Zhonghua baike quanshu* (Concise Encyclopedia of China), and *Aomen baike quanshu* (Encyclopedia of Macao).

**Structures and Processes**

Encyclopedias are arranged mainly by entries that are systematically ordered for easy access. After the editors of an encyclopedia analyze and process the knowledge available—either general knowledge in a comprehensive work, or specific scholarship on the particular subject the work will cover—the headings are designated in such a way as way as to make the encyclopedia “user friendly.” The subjects are then assigned to various scholars or authorities who will prepare the text of the entries. A contemporary encyclopedia can have as few as 1,000 or as many as 100,000 entries. Related entries are often connected with cross-references so that overlapping subjects can be treated without redundancy and related subjects can be associated to each other. Entries often include diagrams, if diagrams, tables and graphics when appropriate, and suggested readings.

Entries are compiled in three ways: by alphabetical order of the first letter of entries, by subject, and by a combination of the first two ways (and with each branch of knowledge contained in a different volume). Encyclopedias of the West often adopt the first method. The *Encyclopedia of China*, nevertheless, employs the last method, the benefit of which is that users find it easy to use and affordable to purchase because they can buy separate volumes as they need.

Apart from the entries that form the main body of text, an encyclopedia also has appendixes to make it more useful. Indexes and appendixes that provide additional information and data, such as maps and chronological tables of important events, are the most important pages of what is called the “back matter.”

**New Media**

Traditional encyclopedias printed on paper have existed for more than a thousand years. With the advent of computer-based information technology in the 1980s, electronic versions of encyclopedias emerged. The early
electronic encyclopedias used a different medium, compact discs. In no time a new type of electronic encyclopedia came into being, one that was interactive and multimedia. This meant that users could not only “talk” to the computer (book) but also could enjoy pictures, audios, and videos alongside the texts. An encyclopedia thus becomes alive and active. If a traditional paper-based encyclopedia is seen as “a university without walls,” then an interactive and multimedia encyclopedia is “a window to a university at home,” which, teaching with three-dimensional demonstrations, gives users enjoyment as they learn.

**Evaluation**

All kinds of encyclopedias with different qualities serve various purposes. A reader must know how to evaluate them and select those that are most helpful. The evaluation should concentrate on four areas: types, functions, readership, and quality. When assessing the quality of an encyclopedia, six criteria should be followed:

- Authority of the writers, editors (editorial board), and publishers responsible for the entries
- Careful selection of complete and up-to-date information
- Objective presentation of views and facts that allows no political, religious, and social biases
- Concise and understandable language
- An easy and precise searching system (the placement of entries and cross-references as well as the creation of indexes)
- Binding and layout, such as the design format, printing, and the quality of paper and binding

**Dictionaries**

Ancient Chinese dictionaries did not differentiate between *zi* (single characters) and *ci* (words with multiple characters). The Chinese called dictionaries of this nature *zishu* (books of characters). Not until publication of *Kangxi zidian* (*The Kangxi Emperor’s Dictionary of Characters*) in the Qing dynasty (1644–1912) and the emergence of the term *cidian* (dictionary of words) in modern China did the Chinese begin to distinguish the concept of *zidian* (dictionaries of characters) from that of *cidian* (dictionaries of words). Nevertheless, the difference between *zidian* and *cidian* is blurred in that a *zidian* may have words as its entries, whereas a *cidian* may also have single characters as its entries. They differ only in their focuses. The English term *dictionary* is, however, indiscriminative of characters and words. There is no such thing as an English *zidian*, or dictionary of characters. The Japanese *ziyin* (pronounced “ziyin” in Chinese) is mostly akin to the Chinese *zidian*.

Pioneering Publications

As early as the second century, Xu Shen compiled his Shuowen jiezi (Explaining Simple and Analyzing Compound Characters), a dictionary arranged in accordance with the structures of each character, which numbered more than nine thousand. It was one of the world’s earliest dictionaries. Then around the time of the Tang dynasty (618–907 CE) Yupian (Jade Chapters) appeared. It consisted of more than twenty thousand characters. Between the Ming dynasty (1368–1644) and the period before the First Opium War (1839–1842) during the Qing dynasty, Kangxi zidian appeared along with another compilation, Zihui (Character Collection), which comprised 33,179 characters. With forty-seven thousand characters, Kangxi zidian is typical of the Chinese dictionaries of characters and remained the largest Chinese dictionary for a long time.

Modern Chinese zidian have been written on the basis of ancient dictionaries of this nature. The most outstanding is the Zhonghua da zidian (Comprehensive Chinese Character Dictionary), compiled by Lu Feikui and others during early Republican China (1912–1949). It not only included more than forty-eight thousand characters, more than the Kangxi zidian did, but also corrected more than two thousand errors in the latter. In 1986 Hanyu da zidian (Comprehensive Chinese Character Dictionary), containing as many as fifty-six thousand Chinese characters, was published. The Zhonghua zihai (Sea of Chinese Characters), published in 1994, records a staggering 85,568 characters.

Comprehensive and Specialized

Because of the different purposes they serve and the different users they target, modern Chinese zidian fall roughly into two major categories. One is the comprehensive zidian, like the Xinhua zidian (New China Character Dictionary), used chiefly for learning and reading the Chinese language. The other is the specialized zidian, such as the Jingdian shiwen (Textual Explanations of Classics and Canons), Gu Han yu changyongzi zidian (Dictionary of Frequently Used Classic Chinese Characters), and Zhongguo shufa da zidian (Comprehensive Chinese Dictionary of Calligraphy). They are written for those who specialize in the study of the forms and pronunciations of Chinese characters.

Commonly used zidian are arranged in three ways: according to the pronunciation of the characters, of their radicals, and of the strokes at each of the four corners of a character in coded numbers. Some zidian use one of the three ways, whereas others use two or all of them at the same time.

Because language constantly changes and new knowledge is continually gained, dictionaries and encyclopedias are destined to be important documents, no matter what their form.

Energy Industry

Coal has been used in China since at least the fourth century; the country has been mainly dependent on it as a source of energy since around 1,000 CE. Today China is the biggest producer and consumer of coal in the world. With increasing demand for energy as Chinese industry grows, the country has been investigating and developing other sources: gas liquefaction, hydroelectricity, renewable power, and nuclear power.

Chinese industry requires energy for commercial purposes such as mining and ore processing; iron, steel, and aluminum production; machine building; manufacturing transportation vehicles such as automobiles, rail cars, locomotives, ships, and aircraft; and for producing or processing textiles and apparel, cement, chemicals, fertilizers, consumer products, food, telecommunications equipment, and armaments. Increasingly, as industries shift manufacturing to China—and China has become the world’s factory—there is also an accompanying shift in energy demand. Energy consumption has been growing 1.4 times faster than the gross domestic product (GDP) since 2001, a growth rate that—barring the impacts of the 2008 global credit and financial crisis—has shown no signs of changing. In some provinces the demand for energy outpaces the supply of coal, oil, and other sources of power leading to imposed brownouts to conserve energy. China is confronted by an energy crisis of enormous proportions: its strategic economic goal of quadrupling GDP by 2020 while only doubling energy growth during the same period is clearly in jeopardy.

According to the International Energy Agency (IEA), the total primary energy supply in thousand metric tons of oil equivalent (ktoe) was 1,717,153 in 2005. On this basis the breakdown of supply consists of: coal, 63.4 percent; oil, 18.5 percent; combustible renewables and waste, 13 percent; gas, 2.3 percent; hydroelectric, 2 percent; and nuclear, 0.8 percent. Geothermal and solar supply is a tiny fraction, not reported in these figures.

Energy Resources

While energy resources are extensive, they will not be sufficient to keep pace with China’s energy needs. The most abundant resource, coal, has a long history of use in China, including heating buildings and smelting metals—going back at least to the fourth century, when coal was simply excavated from surface deposits. Coal was a leading fuel by the year 1000, a time when settlements in Europe still preferred to use wood and charcoal (a fuel made from wood). Coal dominated energy use in China for the next thousand years and continues to do so: China is the biggest producer and consumer of coal in the world. In 2005 China’s coal consumption surpassed 2.2 billion tons.

Eighty-two percent of China’s energy supply comes from coal-fired power plants. Demand for more energy supply reputedly results in the building of a new thousand-megawatt coal-fired power plant every seven to ten days. This reality means that coal industries, rather
than petroleum or natural gas industries, have played the most significant role in energy production and industrial development to date. Apart from the economic benefits, however, much of the coal has high sulfur content, creating widespread atmospheric pollution and health problems, particularly in urban areas. In addition, burning coal contributes to China’s carbon footprint.

The dependence on coal, combined with ample known coal reserves, has led to initiatives in coal gasification and liquefaction to replace coal combustion and oil imports. Coal gasification, which appears to be a promising technology, can lead to production of synthetic gas for power, domestic and industrial heat, and clean fuels for transportation and cooking. Coal liquefaction, a more recent technology, involves coal-to-liquid conversion. Two coal liquefaction plants are scheduled to go into production by 2011, though others have been canceled because of concerns about high capital costs.

In the 1960s increasing concerns about the security of the domestic energy supply, as well as market demands for alternatives to coal, led to major initiatives in oil and gas exploration including the development of the famous Daqing oil field in northeastern China’s Heilongjiang Province. While China does not have significant natural reserves of oil, there are significant domestic reserves of natural gas. For example, the west–east natural gas transmission pipeline, four thousand kilometers long, connects gas fields in Xinjiang and Shaanxi with the Shanghai market. This development will contribute to China’s stated goal of increasing natural gas to 8 percent of total supply by 2010. A second west–east pipeline, running 4,945 kilometers from Khorgos in the northwestern Xinjiang Uygur Autonomous Region to Guangzhou (Canton), the capital of Guangdong Province in southeast China, was announced in 2008. Proven oil and gas reserves on the mainland and offshore, however, will not meet increasing domestic demand. China has become and will continue to be a net importer of oil and gas.

Initiatives to develop untapped hydroelectric potential are underway, of which the Three Gorges hydroelectric dam, created by blocking the Yangzi (Chang) River, the world’s third-largest river after the Amazon and the Nile, has been the most controversial. Not only have there been questions about the economics of the project, its

costs and benefits but also reservations have been raised on environmental and social grounds. The impacts on the riverine environment and ecology as well as the effects of resettling millions of people away from the location of the reservoir and power stations have been massive.

Sources of renewable power—such as biomass, wind, solar, geothermal, and tidal power—are minor in China compared with levels of 3 percent in nations such as Denmark and the United States. Their potential for development, however, is considerable. In recognition of this, the strategic goal for renewable sources is for 15 percent of all energy from wind, biomass, solar, and hydropower energy by 2020, compared with its present 8.5 percent.

Nuclear-power capacity is also expanding. In 2008 there were eleven nuclear-power reactors in commercial operation and another six under construction. Ultimately Chinese authorities seek to be self-sufficient in reactor design, construction, and financing so that they can expand electricity production from nuclear power to 3 percent of total supply in the short term and to 4 percent by 2020.

**Industry Structure**

The shift toward a market economy in energy in China has been fraught with difficulties. National-security concerns over the control of energy supplies and the difficulty of separating government and private enterprise functions in the energy sector represent two overarching challenges at the domestic level. At the international level, the Asian financial crisis of 1997, combined with low prices for oil and coal in the late 1990s, made the economic climate for reforms more difficult at that time. China’s economic reforms since that period have been considerable and include accession to the World Trade Organization in 2001.

The restructuring of the energy industry varies by sector—that is, the type of resource: coal sector, nuclear sector, renewable sector, and so on—with the level of competition significantly less than that in the United States, Canada, and Europe. In January 1994 coal prices were deregulated and gradually allowed to float. This change led to closing thirty-one thousand unprofitable mines in 1999 and another eighteen thousand mines in 2000. Some 420,000 miners were laid off in 1998 alone. Restructuring continues with the planned closure of thousands of small mines, many with poor safety records, before 2010. Mounting opposition from local authorities, however, has delayed the implementation of many closures. Global financial shocks such as the 2008 collapse in credit markets and the prospects of a protracted recession in the United States and the European Union will inevitably lead to less demand for energy by Chinese manufacturers.
The oil and gas industries, like other industries, were once centrally controlled by government. Since the economic reforms of the 1980s, however, state-owned oil and gas companies have been created to increase productive capacity through joint ventures with foreign oil companies. The fact that oil consumption has outpaced domestic production since 1993 has further spurred efforts to increase domestic production. To this end, exploration licenses are now awarded to state-owned (but slightly privatized) companies on a competitive basis to meet national production targets.

The sources of electricity production provide one key insight into the Chinese energy industry. Of the 3.256 trillion kilowatt-hours produced in 2007, about 78 percent was supplied by highly polluting coal-burning plants. The balance came from hydroelectric and nuclear-power industries at about 18 percent and 1 percent, respectively. Other sources, including renewable sources, are not currently significant. The amount of coal used in electricity production is about 24 percent of total coal consumption. Industries such as iron and steel, armaments, cement, and chemical fertilizers also use significant amounts of coal.

The energy reforms that have taken place include the creation of two vertically integrated and publicly traded companies from government-controlled organizations that previously had to serve public-policy and regulatory functions. By creating two “market-based” companies, PetroChina and Sinopec, the Chinese government sought to have greater efficiency in energy production and to prepare the way for the competitive pressures that would arise from greater foreign direct investment in domestic energy projects.

PetroChina was created from the China National Petroleum Corporation (CNPC) in 1999 with 480,000 of its 1.5 million workers. CNPC allocated the majority of its best assets to PetroChina while retaining the excess workforce and welfare obligations. At the outset PetroChina ranked fifth in the world in estimated reserves, produced 68 percent of China's total oil, operated 3,400 gas stations, and owned pipelines transporting 84 percent of China's natural gas. A second company, Sinopec (China Petroleum and Chemical Corporation), followed in 2000. This company operates more than 20,000 gas stations, 1,100 bulk-storage facilities, and a number of refineries. A significant aspect of this restructuring has been the dismissal of 'excess' staff. A 5 percent cut in employment—attributed to soaring labor costs—was announced in 2008, to take effect over a three year period. Given that staff totaled 1.67 million in 2007, this decision would result in 80,000 people losing their jobs. Although information on downsizing is unreliable, it appears that PetroChina laid off 38,000 employees by January 2001 and that Sinopec has cut its workforce of 500,000 by at least 20 percent.

While privatization initiatives are modest given that the state maintains a majority stake in each company, a growing dependence on foreign oil supplies has led Chinese oil companies to a “going-out” or "zou chu qu" policy of overseas investments in oil assets since 2001.

**Challenges**

China’s reliance on coal has led to serious concerns about energy efficiency and environmental problems and makes the development of less harmful sources of energy a pressing challenge. First, energy production is no longer a simple matter of economic efficiency, narrowly defined. Because energy production can have significant impacts on employment and the environment, capital markets are increasingly required to consider environmental, labor, and human-rights ramifications before they make their investment decisions. Second, environmental problems created by burning coal include acid rain, smog, and greenhouse gases such as carbon dioxide. Each of these problems has specific impacts on the environment and human health. Sulfur dioxide causes acid rain, for example, and damages forests, croplands, and lakes. Smog, made up of particulate matter and sulfur dioxide emissions, covers many cities and affects people’s health. In certain parts of China, the concentration of total suspended particles is two to three times the level specified as safe under World Health Organization guidelines. Carbon dioxide emissions (the main cause of climate change through the greenhouse effect) in China are second only to emissions in the United States. The average American creates 7.5 times more carbon dioxide, however, than the average Chinese.

Energy industries, whether they are publicly or privately owned, have not only to produce more energy from existing natural resources; increasingly they also have to produce energy in environmentally responsible ways.

© 2009 by Berkshire Publishing Group LLC
Improving energy efficiency while linking energy production to environmental goals is part of a larger challenge China shares with other nations. Economic efficiency goals have thus become an established aspect of energy strategy. In 2003 China’s energy consumption per unit of GDP was 11.5 times more than Japan’s, 4.3 times that of the United States, and nearly 4 times the world average. The opportunity to reduce the amount of energy and materials consumed is thus enormous. China’s economic efficiency goal, to reduce energy consumption per unit of GDP by 20 percent between 2005 and 2010, was in 2008 the world’s most aggressive energy efficiency target. If China is successful, it will reduce not only the amount of energy required to produce goods and services but also the amount of environmental pollution. As part of this initiative, energy efficiency targets have been set for the thousand largest enterprises that together consume one-third of all China’s primary energy. Benchmarking performance through audits of energy action plans is a key component in measuring whether the enterprises are meeting their energy-saving targets and hence cutting energy use.

The Chinese government’s expectation that GDP per capita will quadruple between 2000 and 2020 poses challenges for the security of energy supply. Rapid economic growth of 8 to 10 percent each year could be thwarted by supply bottlenecks creating energy supply shortages. Whereas 90 percent of the current energy demand can be met from internal supplies, not all the energy required is in a readily available form. This situation is particularly the case for oil, which is mainly imported to fuel transportation vehicles. The imports of crude oil, petroleum products, and some coal are more than twice the exports of the same products and natural gas. Sourcing supplies has thus become a major focus of attention and a diplomatic initiative in its own right. The Persian Gulf, Africa, and Latin America are three geographic areas for future oil and natural-gas imports via maritime shipping. The Russian Federation and central Asia are potential sources of supply for overland pipelines. With regard to coal, when domestic demand is strong, China imports coal from the Association of Southeast Asian Nations and Australia. In many instances, the sources of supply can be interrupted by “pirates,” armed conflict, or trade disputes, suggesting that China needs to follow a diversification policy to spread the risk of interruptions to supply. A shortage of energy is considered not only a threat to economic development but also a potential threat to social stability and national security. Therefore, China adopted a policy goal to build by 2010 strategic oil reserves equivalent to thirty days’ worth of imported oil.

Another aspect of energy security is the control the Chinese government exerts on oil prices. Setting prices lower than those of the international market creates losses for the Chinese oil-refining industry. For example, government-controlled oil prices in the domestic market might create a shortfall in supply as refineries cut production to avoid the losses that arise in buying oil at international prices only to sell at lower government-controlled prices. Producers and dealers might also hoard oil to gain profits in the case of a rise in domestic oil prices. The benefits to consumers can be viewed not only as subsidies but also as the absence of a signal to change consumption behavior.

As a consequence of a variety of concerns, the pressing energy challenge is being addressed through four approaches: structural adjustment, technical improvement, enhancement of management, and focusing on reform. Structural adjustment involves restructuring the industrial, agricultural, and service sectors, particularly through economic efficiency initiatives and the development of non-energy-intensive industries. Technical improvement refers to accelerated research and development of energy conservation technologies as well as technical transfer of new techniques. Improving energy efficiency through enhanced management involves strengthening legal regulations and standards, and energy efficiency labeling and product certification. Focusing on reform involves examining the role of the energy market in regulating supply and demand through more accurate price signals. It also includes implementing preferential tax policies and incentives concerning energy efficiency.

The twin challenges of increasing energy use and reducing environmental pollution pose a serious policy dilemma for China’s continuing economic development and energy industries, a dilemma that is inevitably a driving force behind significant, though possibly rhetorical, commitments to more renewable energy sources and efficiency gains through technological enhancements.

Further Reading

Economic growth, especially as a result of investment in heavy industry, has rapidly increased China’s share of global energy use. Weak enforcement from Beijing and local authorities who appear to opt for profit over environmental efforts emphasize the need for a stronger energy policy in twenty-first-century China.

Between 1978 and 2000, the Chinese economy grew approximately 9 percent annually while energy demand increased 4 percent. At the turn of the twenty-first century, China accounted for 10 percent of global energy demand but met 96 percent of this demand with domestic energy supplies. After 2001, however, economic growth continued apace, but changes in the structure of the economy pushed energy demand up. By 2006, China’s share of global energy use swelled to over 16 percent, forcing the country to rely on international markets for more of the oil, gas, and coal it consumes.

This fundamental shift in China’s energy profile has created both shortages at home and market volatility abroad and raised questions about the sustainability of China’s growth curve. According to the International Energy Agency, China is now the world’s second-largest energy consumer and has likely become the leading source of greenhouse gas emissions.

Evolution of Energy Demand in China

Decades of state planning and ideological aspiration prior to reform in the late 1970s had distorted China’s energy demand profile. Rather than embracing a development strategy compatible with its natural endowments as Japan, Hong Kong, Taiwan, and others had done, Chinese leaders ignored a comparative advantage (that China is rich in labor but poor in capital, arable land, and technology) and dragged China—kicking, screaming, and sometimes starving—toward Soviet-style industrialization. For thirty years, resources sporadically were shifted out of agriculture and into energy-intensive industries like steel and cement. Data from within China claims that between 1949 and 1978, industry’s share of economic output grew from 18 to 44 percent, and the amount of energy required to produce each unit of output tripled.

This command-and-control fiasco resulted in severe inefficiency. In 1978 leaders began to unleash China’s potential. Beijing reformed agricultural production targets and let prices rise, with dramatic results. Farm output increased, and the early 1980s saw rural residents with more time on their hands, cash in their pockets, and freedom to use it as they chose. Much of this new wealth was invested into township and village enterprises (TVEs) set up to exploit what China was best suited for: labor-intensive light manufacturing.

Reform also brought changes within heavy industry, which reduced the energy intensity of Chinese growth.
Economic incentives—such as the right to keep profits—were introduced, and awareness of bottom-line profits made enterprises focus more on top-line expenses, including energy. As enterprises were becoming more aware of the impact of energy costs on profitability, their energy bills were growing as a result of the partial relaxation of oil, gas, and coal prices. The introduction of limited competition for both customers and capital, not just from other state-owned enterprises (SOEs) but also from a growing private sector, made energy cost management all the more important. Domestic competition was accompanied by a gradual integration with world markets; lower trade barriers not only exerted pressure on SOEs from energy-efficient foreign companies but also allowed them to acquire the more energy-efficient technology their competitors enjoyed. China’s small existing base of modern plants and equipment enabled it to absorb new technology quickly, significantly improving the efficiency of the country’s capital stock.

By 2000, Chinese economic activity required two-thirds less energy per unit of output than in 1978. Energy intensity improvement on this scale was unprecedented for a large developing country, and it meant that in 2001, China accounted for 10 percent of global energy demand rather than the 25 percent that had been projected based on its 1978 energy performance.

**Investment-Led Energy Surprise**

At the start of the new millennium in 2001, China’s leaders expected the energy intensity improvements that had been taking place since 1978 to continue. Most energy forecasters at home and abroad assumed that the structural shift away from energy-intensive heavy industry would persist; at least, no one expected the evolution to reverse quickly.
In 2001 both the Chinese government and the International Energy Agency (IEA) predicted 3 to 4 percent energy demand growth between 2000 and 2010.

In actuality, both wildly missed the mark. The economy grew much quicker than anticipated from 2001 to 2006, but the real surprise was a change in the energy intensity of economic growth: Energy demand elasticity (the ratio of energy demand growth to gross domestic product, or GDP, growth) increased from 0.4 (during 1978–2001) to 1.1 (2001–2006). In 2006, energy consumption in China grew to 16 percent of global demand, four times faster than predicted. And yet on a per capita basis, China’s energy demand remains one-sixth that of the United States, triggering anxiety about how much more growth is yet to come.

This discovery not only shocked domestic and international energy markets but also prompted a fundamental reassessment of China’s energy future—and hence the world’s. In its 2007 World Energy Outlook, the IEA raised its 2030 forecast for China’s energy demand to 3.8 billion tons of oil equivalent, up from the 2.1 billion tons it had predicted in its 2002 outlook—a 79 percent upward revision. Under this scenario, China will account for 22 percent of global energy demand, more than Europe, Russia, and Japan combined, easily surpassing the United States as the world’s largest energy consumer.

What caused China’s two-decade history of energy intensity improvements to change course? Many authorities assume that the recent evolution of China’s energy profile reflects growth in consumption and transportation—for instance, air conditioning and personal cars—but this is not correct. Consumption-led energy demand will be a major force in the future, and it is already significant in absolute terms, but the main source of current growth is energy-intensive heavy industry. Industrial energy efficiency has continued to improve over the past six years; every new steel mill is more efficient than the last one. But the late-twentieth-century structural shift away from heavy industry toward light industry has reversed, and a new steel plant—no matter how much more efficient than its predecessor—uses substantially more energy than a garment factory. The IEA asserts that industry accounts

Technicians in an observation booth at a heavy machinery plant in Beijing.

PHOTO BY JOAN LEBOLD COHEN.
for two-thirds of final energy consumption in China today, while the residential, commercial, and transportation sectors account for 12, 5, and 13 percent, respectively.

This industrial energy consumption is high by either developed or developing country standards. (See Table 1.) But when pundits express shock at how much more energy intensive China is than Japan, for example, they usually ignore the important factor of what the country makes. High energy-intensity partly reflects the role of industry in the Chinese development model, as opposed to India, which has taken a more services-heavy approach, or Japan, which has lowered its energy intensity in part by relocating its energy-intensive sectors to China. According to Chinese statistics, industry accounts for 48 percent of all economic activity in China, compared with India at 29 percent and Japan at 26 percent. So the fact that one unit of economic output requires five times as much energy in China as in Japan says more about the type of economic activity taking place in China than the efficiency with which it occurs.

Increasingly, economic activity in China is slanted toward capital investment, and from an energy standpoint, the current investment cycle is different than in the past. Rather than importing, China is now producing domestically more of the energy-intensive basic products (such as steel and aluminum) used to construct the roads and buildings for which investment pays. China now accounts for 49 percent of global flat glass production, 48 percent of global cement production, 35 percent of global steel production, and 28 percent of global aluminum production. Some of this production also reflects the migration of industry from other parts of the world not only to meet domestic demand in China but also for export. Whereas China used to be a net importer, it has now become a major global exporter of steel, aluminum, and cement.

The changing composition of China’s industrial structure is also a result of competition among provinces and localities to grow GDP, tax revenue, and corporate profits. Not just Beijing but also local interests (including industrial enterprises) set the rules of competition. And regardless of who sets the rules, implementation is a local matter. Within this context of competition, short-term economic incentives—specifically low operating costs and profits—explain much of the increase in heavy industrial activity.

After-tax earnings in energy-hungry industries have been good, rising from near zero in the late 1990s to a level comparable to that of their light-industry counterparts—ranging from 4 to 7 percent in steel, glass, chemicals, and cement in recent years. With China modernizing over 170 cities of more than 1 million people, certainly there is a large domestic market for basic materials; supply was squeezed by breakneck growth after 2001. But with over-capacity arising almost as soon as the first profits come in, the ability of firms to sell surplus production in international markets has been critical to remaining profitable.

China’s energy-intensive industry enjoys low operating costs, which has allowed for rising profit margins and a dramatic growth in capacity that is at the center of China’s overinvestment in heavy industry.

*Note:* This table excludes biomass but includes nonenergy use of energy commodities.

governments often provide deeply discounted land, and they often do not enforce regulations to protect air and water. Construction time is short, and labor costs are low. These benefits apply to all industries, however, they are particularly valuable in the energy-intensive sector, where capital costs are large.

**Energy Prices and Environmental Costs**

Energy prices in China, once highly subsidized, have gradually converged with world prices over the past thirty years. Yet, it can be difficult to accurately assess the price a specific firm pays for coal, gas, oil, or electricity. Chinese prices for raw energy commodities (including coal and natural gas), particularly in interior provinces close to resource deposits, can be significantly cheaper than elsewhere in the world. For coal, low prices result not from subsidization but rather from low extraction costs in areas isolated from international markets; as obstacles to transportation ease, coal prices will rise toward world prices. Beijing also directly controls natural gas prices, attempting to keep them competitive with the Middle East. But this approach has failed to encourage development and delivery of sufficient quantities of natural gas to meet demand, and authorities are allowing domestic prices to increase.

China’s industry increasingly receives its energy in electrical form, and reported prices of electricity are high compared with those in developing and some developed countries; only in Germany, the United Kingdom, and Japan are costs greater. However, based on conversations with Chinese business leaders and industry analysts, it is likely that many industrial enterprises do not bear the full cost provided by national average figures from the Statistical Bureau. China’s National Development and Reform Commission (NDRC) sets electricity tariffs province-by-province based on the recommendations of local pricing bureaus, which answer to local officials. While the NDRC would like to see energy pricing rationalized to reduce overall energy consumption, it is sensitive to local social and economic development concerns.

Energy prices in China have not reflected environmental costs historically. Over 80 percent of the country’s electricity is generated from coal. But at the end of 2006, less than 15 percent of coal power plants had flue gas desulphurization (FGD) systems (used to remove sulfur dioxide from emissions streams) installed and even fewer had them running. Operating an FGD system reduces production efficiency by 4 to 8 percent and therefore contributes to higher electricity prices. If all the power plants in China installed and operated FGD systems, average electricity tariffs could rise by 10 to 20 percent. Industries that burn coal directly (such as steel and cement) are subject to sulfur taxes, but these are generally too low to reduce pollution. Other air pollutants, such as nitrogen dioxide and mercury, are largely unregulated. Regulated or not, enforcement generally falls to the provincial and local governments, which must balance environmental concerns against economic growth priorities. In the absence of a strong environmental regulator, like the U.S. Environmental Protection Agency, that balance is skewed toward near-term economic growth, as industry threatens to cut jobs and tax revenue if enforcement of environmental regulations is increased.

While it is a daunting and subjective challenge to compute the external impacts of China’s penchant for heavy industry, it is important to recognize that they exist: China does not necessarily do the world a favor by overproducing. Moreover, there are other effects to be considered. A rebalanced China, better aligned with its natural endowment of labor, could be a bigger economy, grow faster, and be less prone to collapse; hence it would be a better engine of world growth. Also, heavy industry in China is less likely to attract innovation and technological change due to weaknesses in intellectual property protection and the difficulty of recovering research-and-development investments. Similarly, institutional weaknesses in regulation and enforcement of pollution controls undermine the process of finding innovative ways to remedy environmental damage.

Like the United States, China needs oil to fuel its economy, but with the United States now in a position of influence in Iraq, China has had to turn to countries such as Sudan and Iran to meet its needs—precisely when the United States has sought to isolate these nations.

Like terrorism, weapons of mass destruction (WMD), and other security issues facing nations today, energy supplies—especially oil supplies—have become a major security challenge. This challenge is especially important to China because of the country’s rapid growth and urbanizing population and because competition—or potential competition—with China for energy resources and control of them has become a serious concern for the United States.

China’s competition with the West for the global supply of oil is the latest addition to the list of factors comprising a “China threat.” Older factors include China’s aggressive drive for industrial and economic power, its rapid military buildup, and its authoritarian regime’s determination to maintain its grip on power and continued disregard for human rights. Many consumers in the United States believe that China’s voracious demand for oil has contributed to the increases in U.S. gasoline prices. Those who advance this claim argue that China’s ambitious energy policy is part of a plan to become a superpower and ultimately to replace the United States as the next hegemon (influence) of East Asia and the world.

But the alternative claim is that China survives by keeping its economy growing and its huge population working—and oil is necessary for that.

China has averaged 9.4 percent annual growth of gross domestic product (GDP) since 1978. At that rate China’s economy doubles every ten years. China’s combined share of world consumption of steel, cement, aluminum, copper, nickel, and iron ore more than doubled between 1990 and 2000 (from 7 percent to 15 percent). Only twenty years ago China was Asia’s largest oil exporter. In 1993 it became a net importer of oil, and in 2004 it became the world’s second-largest oil importer and consumer after the United States. Since 2000 China has accounted for 40 percent of the world’s growth in demand for crude oil.

Several factors have contributed to the explosion in China’s demand for oil: rapid industrialization, growing automobile ownership, increasing air travel in and outside of China, expanding export processing, to mention a few. China’s domestic oil production provides about two-thirds of its crude oil consumption; the balance must come from imports. Studies predict that by 2050 at the latest and perhaps even by as early as 2025 China will import 80 percent of its oil.

Beijing has developed several strategies to cope with its growing need for oil. These strategies include increasing exploration at home, diversifying its sources of energy and developing alternative or renewable sources of energy (China would like to be the world’s largest producer of nuclear energy by 2050), rationing, developing energy-friendly technologies such as hydrogen-powered fuel cells, building strategic petroleum reserves, and acquiring new stocks and oil fields overseas.
China’s focus has been on acquiring foreign oil assets. China’s quest for sources of oil beyond its borders has four main characteristics. First, the occupation of Iraq by the United States has forced China to consider sources of oil beyond the Middle East. Second, because China cannot afford not to consider all sources of oil, it does business with “rogue regimes” and has intruded on regions that fall under U.S. hemispheric influence. Third, China’s global energy networks demand that China develop naval power in the long term to secure its sea lanes. Fourth, however, because China lacks that naval power, Beijing’s intermediate security strategy is to pursue a “go west” policy in central Asia and to invest in a “string of pearls”: countries that are geographically contiguous to China.

**China’s Oil Needs and the Iraq War**

Until recently 60 percent of China’s oil imports came from the Middle East, which contains two-thirds of the world’s reserves. Saudi Arabia, the world’s largest oil producer, is China’s largest oil supplier. China’s largest oil company, China National Petroleum Corporation (CNPC), had been waiting to develop the Al-Ahdab reserves in central Iraq as well as the even larger Halfayah oil field. These two oil fields would have supplied 13 percent of China’s domestic consumption. But the 2003 Iraq War and the continued occupation of Iraq by the United States have dashed the hopes of CNPC. In addition, Iraq borders five of the world’s largest oil producers. This fact of geography means that the United States has greater leverage in the Persian Gulf than ever and that China’s future in Middle East oil has become more tenuous.

To China’s detractors Beijing has been indiscriminate in doing business with those regimes that Washington has identified as “rogue” or “pariah”—Iran, Sudan, Uzbekistan, and Myanmar (Burma), for example. China’s initiatives conflict with U.S. attempts to contain these regimes. For instance, when the United States severed ties with Sudan after the 1997 genocidal war against Christians in the Darfur region, Beijing made Sudan its largest oil producer. This fact of geography means that the United States has greater leverage in the Persian Gulf than ever and that China’s future in Middle East oil has become more tenuous.

In short the competition for oil has accented and increased the differences in U.S. and Chinese foreign policy objectives and stances on how the international system should be run. In exchange for oil China supplies economic assistance with no political strings attached and in so doing has begun to rewrite the rules of the system.
Not only Latin America but also Africa (where, in addition to Sudan, China has invested in oil-rich nations such as Equatorial Guinea and Nigeria, among others) has benefited from China's economic growth in terms of investment and trade. China is now the main stimulus for export growth in those regions. In general Chinese investments in infrastructure and developmental aid are raising standards of living in the developing world. That has been China's ambition since the 1950s.

Necessity of Naval Power

China, because its drive for oil security has taken it to every corner of the Earth, eventually will have to develop a world-class navy to secure its sea lanes to ship oil. China will have to develop a blue-water navy (that is, a navy that can operate freely in the deep ocean away from the Chinese mainland) with global reach, and that navy must match U.S. naval capabilities in the long run. The current situation, with the United States having naval supremacy and controlling the global sea lanes of communication, is dangerous to China because the United States can easily threaten China's security. For instance, the United States could impose an oil embargo on China in the event of a conflict in the Taiwan Strait between Taiwan and the PRC.

Opinions vary on how rapidly China is transforming its mainly coastal navy into an oceangoing navy. China is attempting to acquire strategic nuclear submarines, attack submarines, modern surface vessels, and so forth both through purchases (primarily from Russia but also from Europe and Israel) and through a domestic shipbuilding program. However, China knows that it is so far behind the United States in naval capability that it is also investing in oil pipelines that carry oil via land from Southeast and central Asia.

Two Alternative Geostrategic Plans

China is relying on two medium-term strategies to compensate for its lack of a blue-water navy. The first strategy is its "go west" policy of acquiring assets in central Asia. China's longest pipeline, the 4,200-kilometer Tarim Basin-to-Shanghai gas pipeline, began operating in 2004. Construction of a 988-kilometer pipeline from Kazakhstan to Xinjiang is almost finished. China also is helping to develop oil fields in Uzbekistan. But the success of the "go west" policy has been mitigated by an increased U.S. military presence in the area because of the terrorist attacks of September 11, 2001, greater competition from India, and various overlapping power blocs.

The second strategy is to build a series of strategic bases—a "string of pearls"—along the major sea lanes from the South China Sea to the Arabian Sea. The goal is to construct an alternate oil importation route that avoids the Strait of Malacca, through which 80 percent of China's oil imports flow. China is fortifying bases in the South China Sea to allow large-scale deployment of air force and naval units on Hainan Island as well as constructing facilities on the Spratly and Paracel Islands to accommodate strategic bombers. In essence China is building a group of unsinkable aircraft carriers in the South China Sea.

Farther west China is constructing container port facilities at Chittagong in Bangladesh and intelligence-gathering facilities and naval bases on Myanmar's islands in the Gulf of Bengal. China also is constructing a pipeline from Sittwe in Myanmar to its own Yunnan Province. China has other projects under way in Pakistan and Thailand. Unfortunately for China, it is not without rivals in these regions either. In Southeast Asia China has to compete with India; in the South and East China Seas it has to compete with Japan.

A Unique Predicament

If China's oil supply were cut, its economy probably would come to a standstill. That likelihood increases as China's dependency on imported oil increases. China's predicament is difficult for two reasons. First, China is undergoing the equivalent of the Industrial Revolution—150 years late. China, as a relative latecomer among the pantheon of global powers, has had to play by some of the rules established by Western powers. But China is beginning to rewrite other rules. In a world where there is no arbiter of conflicts over limited natural resources, China, like all other nations, must defend its national security and interests.
Second, China’s population and size make its geostrategic problems unique. Its energy concerns cannot easily be shared with others. Japan and the United States have sufficient military capabilities to protect their supplies. Moreover, the United States enjoys an insular continental position, whereas China borders fourteen countries. If the United States, given that insular position, is concerned about terrorist infiltration, imagine China’s concern for its situation. China’s landmass is third largest in the world (after Russia and Canada), but China’s population is greater than that of Russia, the United States, Japan, and the European Union combined.

Chinese manufactured goods are enhancing the lives of countless people on the planet. To a large extent the United States and other countries depend on the continued health and growth of the Chinese economy. China needs to have the natural resources to continue to produce its goods. No one benefits if China’s economy collapses due to the lack of oil. The global community should keep these facts in mind as it faces the challenge of China’s rising demand for oil.

Anthony A. LOH

Further Reading

With increasing energy demand and limited conventional energy resources, China is recognizing the need to develop renewable energy. In 2007, the consumption of renewable energy accounted for 8.5 percent of the country’s total primary energy consumption. In order to improve renewable energy development, the government has taken a series of countermeasures and has issued some related regulations.

China is one of the largest energy production countries in the world; it is also one of the largest energy consumption countries in the world. In 2007, China’s total commercial energy production reached 2.35 billion tce (ton-of-coal equivalent) among which coal production accounted for 76.6 percent; crude oil 11.3 percent; natural gas 3.9 percent; and the aggregation of nuclear power, hydropower, and wind power generation 8.2 percent. In terms of consumption, in 2007, China’s aggregate energy consumption reached 2.66 billion tce, 7.8 percent more than in 2006. Of the total consumption, coal accounted for 69.5 percent, while petroleum accounted for 19.7 percent; natural gas accounted for 3.5 percent; and the aggregation of nuclear power, hydropower, and wind power accounted for 7.3 percent (NBSC, 2008). The net imported petroleum reached 184.8 million tons in 2007; the rate of dependence on import reached 50 percent. As a result of increasing energy demand, the share of coal in total energy consumption was increased by 0.1 percent from 2006 to 2007.

The United States is the world’s largest energy producer, consumer, and net importer. It also ranks eleventh worldwide in reserves of oil, sixth in natural gas, and first in coal (EIA, 2008c). In 2007, primary energy production in the United States reached 2.58 billion tce: coal accounted for 32.8 percent, natural gas 27.7 percent, crude oil 15 percent, NGPL (Natural gas plant liquids) 3.4 percent, nuclear electric power 11.7 percent, renewable energy (including hydropower, geothermal, solar/PV, wind and biomass) only 9.5 percent. Primary energy consumption reached 3.66 billion tce: coal accounted for 22.4 percent, natural gas 23.3 percent, petroleum 39.2 percent, nuclear electric power 8.3 percent, renewable energy (including hydropower, geothermal, solar/PV, wind and biomass) 6.7 percent (EIA, 2008b). The United States imported about 58 percent of the petroleum, which includes crude oil and refined petroleum products, that it consumed during 2007 (EIA, 2008a).

Challenges and Opportunities

China is facing many challenges concerning the production and use of traditional energy, which in turn are yielding great opportunities for expanding sources of renewable energy (Asif and Muneer, 2007). Energy, on one hand, is an important foundation for the development of China’s socio-economy. Since implementing the reform and expanding...
market policies in the early 1980s, the nation’s energy sector has made great achievements. Over past three decades, China’s energy supply has generally kept pace with the demands of the growing national economy.

The long-term energy bottleneck issues, on the other hand, have always existed in China. Since the sixteenth Chinese Communist Party Congress (CCPC) put forward the goal of building a well-off society, the initiative of all communities to promote economic development rose to an unprecedented level, and the pace of national economic development accelerated. As a result, since 2002, energy supply-and-demand problems have emerged again. For example, the coordination between the transportation, supply, and the demand for coal, electricity, and oil have become a great challenge. The phenomenon of “limited power supply” is occurring over large areas around the country owing to the shortage of coal power. Oil imports have increased greatly. It is widely acknowledged that the energy shortage has become a critical factor, limiting the nation’s socioeconomic development. In the long term, the energy issue will be one of the most serious problems facing China.

In terms of the current energy supply and demand, China is facing three main problems:

1. Extremely limited energy resources: China’s total proven reserves of conventional energy sources is about 820 billion tce. Its proven remaining exploitable reserves are 150 billion tce, about 10 percent of proven remaining exploitable reserves in the world. In terms of average energy consumed per capita, the China uses only 70 percent of the world average, while the petroleum consumed per capita is 10 percent of the world average, and natural gas consumed per capita is 5 percent of the world average. China’s hydropower resources are relatively abundant. Both the total theoretical capacity and economically exploitable capacity of hydropower are the largest in the world. It should be noted, however, that the exploration of hydropower resources is tremendously restrained due to the environmental impacts, floods loss, migration, and many other issues.

2. Dependence on coal, which is causing serious environmental problems: China is the world’s largest coal consumer, accounting for 40 percent of world consumption in 2007 (EIA, 2008b). Coal meets nearly 70 percent of China’s primary energy needs. At present, the coal-dominated energy structure has caused substantial impacts on the ecological environment. China ranks second in the world to the United States in carbon dioxide emission, while China’s emission of sulfur dioxide is estimated to be first in the world. Clean-coal power-generation technologies must be developed to gradually reduce the proportion of coal consumption in the overall energy structure.

Coal mined in China produces more of China’s energy than any other fuel, but it is not a renewable resource. Hillsides have been stripped by coal mining, depleting the supply, and China’s coal-dominated energy structure has caused substantial impacts on the environment. PHOTO BY JOAN LEBOLD COHEN.
3 Low technical levels in energy utilization and low efficiency of energy use: China’s fast economic growth is, to a large extent, dependent upon the great amount of consumption of various physical resources. The energy consumption per unit output in China is clearly much higher than international advanced levels. Coal consumption from coal-fired power plants per unit output, for example, is 22.5 percent higher than other advanced levels in the world.

China, of course, will have a continuing thirst for energy. The World Energy Outlook 2007 published by the International Energy Agency forecasts that total energy consumption in China in 2015 will be about 2.85 billion toe (tons of oil) and about 3.82 billion toe in 2030 (IEA, 2008). In addition to restructuring its economic growth, increasing energy efficiency, and building an energy-conserving society, special attention continues to be given to the development and use of China’s abundant, inexhaustible, and environmentally friendly renewable energy resources.

Development

In 2007, the consumption of renewable energy in China totaled 220 million tce, accounting for 8.5 percent in the total primary energy consumption (Zhao et al., 2008). But China has abundant renewable energy resources, and the potential for developing and utilizing these resources is very great. The main types of renewable energies in China include hydropower, wind power, biomass energy, solar energy, geothermal energy, ocean energy, and others. Despite disagreement about hydropower internationally, it is widely agreed that small hydropower (SHP) is a valid source of renewable energy. In the case of China, those hydropower stations with a capacity of less than 50 megawatts fall into the SHP category.

China has the theoretical potential for ranking number one in small hydropower development, with resources located in 1,600 counties (or cities) across thirty-one of China’s provinces (and provincial level municipalities, excluding the Taiwan, Hong Kong, and Macao). Small hydropower resources are particularly plentiful in southwest China, where over 50 percent of the total SHP
resource base is located. China’s technology for hydropower station design, installation, and operation is quite mature, and it has installed more than 80 percent of its hydropower capabilities, with roughly a third coming from small hydropower sources (Shi, 2008), (REN21, 2008).

Wind resources are particularly rich in northeastern China, northern China, northwestern China, and the eastern coastal regions. By the end of 2007, Germany had the largest wind power capacity in world, while China ranked fifth, with over 158 wind power farms on the mainland. The manufacturing technology and capabilities of China’s wind power equipment have also greatly improved, as has the volume of their production.

China enjoys the availability of plenty of solar energy. Most of China’s land area is located south of 45°N latitude. Over two-thirds of China’s land area receives over 2,200 hours of sunshine per year, with a total solar radiation received by China’s land areas annually being equivalent to 1.7 trillion tce. At present, solar energy is mainly applied in two areas, solar thermal and photovoltaic (PV). By the end of 2007, China had installed PV power to supply electricity for residents in remote rural areas and for transport and communication stations.

In recent years, China’s solar water heater (SWH) industry has been developing very quickly and has already become quite competitive. China’s export of solar water heaters, boosted by demand in the international market, also rose. In 2007, China’s export value of solar water heater increased by 28 percent from 2006 to equal US$65 million (CBI, 2008).

Biomass energy resources mainly consist of wastes from agriculture and forest industries, industrial wastewater, animal and human manure, and municipal solid wastes. China is a major agricultural producer, and biomass wastes from agriculture are widely distributed, especially those from crop stalks. Fuel-wood forests, timber-processing industries, and other forestry sectors generate biomass waste of over 600 million tons annually, of which 300 million tons can be used in energy applications. The industrial wastewater and manure from livestock and poultry farms are a substantial source of biogas. China’s cities are predicted to produce about 210 million tons of municipal solid waste by 2020. Once land-filled and waste-combustion power generation technologies are implemented, the annual energy produced could be 15 million tce. According to preliminary estimates, the total exploitable annual capacity of biomass energy in China is 500–800 million tce from now to 2030 (NDRC, 2007).

Incentives

Realizing the great importance and huge potentials of renewable energy, the Chinese governments have implemented a series of policies to promote sustainable development. At the level of macro-policies, the National People’s Congress had already promulgated China’s Renewable Energy Law by February 2005. Critical systems were established in the law: (1) a system of government responsibility, requiring the government to formulate development targets and strategic plans, and to guarantee measures for renewable energy; (2) a system of public cost-sharing (realized by a cost-sharing system of the grid), whereby all citizens will be required to share the extra costs associated with developing renewable energy; and (3) a system of punishment and reward, which was designed to encourage the entire society, particularly companies, to develop and use renewable energy, and has financially punished those companies and individuals that have not met the obligations set out for them in the law (NPC, 2005). In addition, some specific regulations, legislation, and standards to implement the law have been constituted. In particular, the medium- and long-term
development plan of renewable energy in China was issued in 2007. Clearly, the legal system to develop renewable energy has built a preliminary foundation.

Some direct economic incentives have also been implemented to encourage the development of renewable energy industry in China. First, is the customs tariff relief. Customs duties on imported complete wind turbines are 6 percent, whereas duties charged on imported components of wind turbines is 3 percent. Second, some value-added tax (VAT) is waived. Currently, most renewable energy products are taxed at the full VAT value (unified VAT rate is 17 percent). The exceptions are rates of 13 percent for biogas generation, 8.5 percent for wind power, 6 percent for SHP, and 0 percent for municipal solid-waste power generation. A third incentive is loan savings. Discounted loans were aimed to support biogas projects, solar-thermal applications and wind-power generation technologies. The government offered a 50 percent discount on regular commercial bank-loan interest. In addition, the government made a limited number of low-interest loans available for SHP. Some wind companies have benefited from the discount loans for the first 1 to 3 years. Fourth, central authorities offered subsidies in research and development (R&D) and marketing demonstration, as well as some local subsidies for solar energy systems for homes and for small wind systems in rural regions.

In addition to the central governments incentives, local governments have also formulated their own preferable measures. For example, income tax from wind companies was waved for the first two years in Inner Mongolia, and from 50 to 200 yuan was subsidized to each home PV system or small wind turbine.

Obstacles

Ironically speaking, some barriers to renewable energy development have indeed existed in China. Although the Chinese government has issued some policies to promote the development of renewable energy over the past ten years, the share of renewable energy in the total primary energy consumption is still low. Breaking the barriers that obstruct renewable energy development in China will be significant to China’s energy future.

First, the government must apply some incentive measurements to promote renewable energy in its initial stage. At present, the policy system to support renewable energy such as wind energy, bio-energy and solar energy is imperfect; the incentive measure is not enough, the implementing of policies is poor, and policies are unconnected. The absence of effective investment and financing mechanisms greatly restrain the R&D processes. Owing to the characteristics of high cost, diffuse distribution, small-scale and discontinuous production, most renewable energy still lacks competitive capability in comparison with conventional energy technologies. Therefore, an integrated, powerful, stable, effective stimulus combined with incentive mechanisms based in law is necessary for further development.

Second, the market mechanism is imperfect. As a result of the above-mentioned characteristics and the absence of a definite long-term target to develop renewable energy, a continuous and stable demand for renewable energy in China has not yet emerged. The driving force of the market is so limited that technological innovation of advanced renewable energy has moved slowly. A few technologies, such as SHP and solar water heater, have to some extent, realized commercialization after years of improvement, though their market share is still very small compared to their entire potential and total energy demand. To further expand the market, there is a need to decrease the production cost and improve technology reliability.

Finally, the technology and industrial system is still fragile. Excluding hydropower, solar water heaters, and biogas, the investment in R&D in most renewable energy remains low, and China’s production capacity is inferior to that of developed countries. In addition, some key technology and devices have depended on imports for many years, such as the PV module production lines and large wind turbines. Moreover, there are no professional, accurate and integrated evaluation systems, and there is no quality control system. The human resource training system and technology service systems are imperfect due to the shortage of communication, and dissemination of information about renewable energy.

It is clearly expected that the development of renewable energy has stepped into a crucial phase in China. In next twenty years, whether renewable energy can be developed on an industrial scale will depends on support of further preferable policies and market expansion.

Enterprise Income Tax
Qǐyè suǒdéshuì 企业所得税

The Enterprise Income Tax (EIT) is a tax law that came into effect in China on 8 January 2008. The law replaces an earlier, more complicated system that used a Western-style tax system for foreign-owned firms and another system for Chinese-owned firms. The State Administration of Taxation’s regulations of the law are available to the public.

Following the creation of the People’s Republic of China in 1949, China’s tax system was based on a Soviet-style economic model since there was no private business sector to speak of. Industry and commerce were controlled by publicly owned enterprises. State-owned enterprises delivered all their profits to the central government. The only real tax was a type of sales tax that was used to facilitate the transfer of funds from enterprises to the central government.

Tax Reform
Starting in the 1980s, as China began its move toward a socialist market economy, a number of major tax reforms were introduced. Today the Chinese tax system looks like many other countries’ tax systems, although many uniquely Chinese features remain. For instance, there is a two-track system, the foreign track and domestic track, each with different regulations and types of administration. With respect to deductible expenses, for example, foreign enterprises can deduct the cost of wages, salaries, and employee benefits, whereas domestic enterprises can deduct only the amount of wages in accordance with the standard set by the government.

China’s tax system consists of various consumption taxes, income taxes, property taxes, and miscellaneous taxes. One such income tax is the enterprise income tax. China implemented a dual-track system of enterprise income taxation from 1979 to 2007: a Western-style tax system for foreign-owned firms and another system for Chinese-owned firms. As of 1 January 2008, this dual-track tax system ended and a new Enterprise Income Tax (EIT) law became effective for all forms of enterprises.

The process that culminated in the promulgation of the EIT took thirteen years but was relatively transparent compared to most policy changes in China. Early drafts of this tax law were widely debated and commented upon. The structure and substantive provisions of the EIT legislation are more sophisticated than its predecessors were; for example, the threshold of tax incentives is more detailed. Explanatory notes on EIT regulations by the State Administration of Taxation (SAT) are detailed and insightful but, more importantly, available to the public.

Objectives
In addition to the obvious goal of raising government revenues, the EIT legislation was introduced to achieve the following objectives: to ensure equitable taxation of all businesses by ending systematic and serious discrimination against Chinese-owned businesses; to promote sustainable economic development of China’s economy; to
be consistent with international tax norms and practices; and to improve efficiency in tax administration.

The EIT has become an important instrument in China’s plans to promote sustainable economic development. Attracting direct foreign investment to China remains a key policy concern. Instead of providing specific tax incentives, as do tax policies in other countries, the EIT has adopted an internationally competitive tax rate. The tax incentives are targeted at investments in small and high-tech businesses, as well as projects in agriculture, forestry, animal husbandry, fisheries, job creation, public infrastructure, environmental protection, water and energy conservation, research and development, and technology transfer.

Fundamental Principles

The EIT is based on a set of fundamental principles enforced by the EIT Law and its regulations. Administrative matters related to the EIT are contained in the Tax Administration and Collection Law. EIT legislation states that a taxation year is the calendar year and that no consolidation is allowed for enterprise groups unless specifically authorized by the State Council.

The determination of taxable income is primarily a legal question. Although financial accounting is the basis for the computation of income or loss, the ultimate determination must be governed by the provisions of the EIT Law. These legal provisions override any inconsistent financial accounting principles. Revenues and expenses must be recognized in accordance with the accrual method of accounting, which recognizes income when earned and expenses when incurred regardless of when cash is received or disbursed. The principle of truthfulness requires that revenues and expenses be supported by evidence, typically invoices or receipts. The principle of substance over form requires that transactions be characterized for tax purposes in accordance with economic substance, not the legal form. The principle of realization requires that income be recognized only when it is realized, that is, when the income-earning transaction is completed.

International Tax Norms

The Chinese enterprise income tax system has undergone major reforms since the 1980s. A Western-style income tax, known as the Chinese–Foreign Joint Venture Income Tax (JVIT), was first introduced in 1980. Foreign tax terminology, structures, and concepts found their way into the JVIT, but the Chinese characteristics were overwhelmingly present. For instance, tax expenditures for social programs and subsidies are much less than they are in the West. Most taxes go toward government expenditures. China’s financial system is highly decentralized. Expenditures by local governments account for 71 percent of government expenditures. The central government has exclusive taxing powers in terms of legislation. All taxes
are introduced by the central government. However, revenue from specific taxes is assigned to local governments. Overall, local governments receive about 50 percent of total tax revenues. Since 1980, the trend has been more toward internationalization as the Chinese economy has moved closer to a market system.

The Chinese have always adapted foreign ideas to meet Chinese needs. To the Chinese, because the market economy originated in the West and the market demands rational laws, which are predominantly Western laws, it was important to transplant Western laws to China and to harmonize Chinese laws with international norms. Tax laws directly affect the market, and enterprise income taxes were seen as less politically and culturally sensitive than income or sales taxes, so the process of internationalization was relatively quick.

**TAX ADMINISTRATION**

The new EIT legislation significantly improves the efficiency of tax administration. It provides more certainty and predictability through more detailed and clearer rules for qualifications for tax incentives. In contrast, the previous system authorized the tax authorities to preapprove the qualification of eligible enterprises for tax incentives, leaving a great deal of discretion to local tax officials. The EIT also introduces new anti-avoidance rules that send a signal to taxpayers about unacceptable tax avoidance transactions. The typical examples of anti-avoidance rules involve transfer pricing and thin capitalization.

**Features of the EIT Tax Law**

Not surprisingly, the EIT system contains many regulations and requirements, exemptions and exceptions. Following are some of the key features of the EIT legislation.

**TAX LIABILITY**

Enterprises are subject to the EIT if they are residents or nonresidents earning income from a Chinese source. Resident enterprises are subject to tax on their income from inside and outside China, whereas nonresident enterprises are subject to tax only on their Chinese-source income.

**TAXABLE ENTERPRISES**

Under the EIT Law, all enterprises, regardless of ownership, are subject to the same tax rules. The term enterprise, however, is somewhat vague in the EIT legislation. According to the State Administration of Taxation (SAT), enterprise includes, but is not limited to, a corporation. The key is whether an enterprise is a legal person under Chinese civil law. (In legal terms a legal person is an individual, a group of individuals, or even the state that can make claims against other legal persons and have those claims resolved in court.) In addition, some nonprofit entities are treated as enterprises under the EIT legislation. On the other hand, a sole proprietorship or a partnership established in China is specifically excluded from the meaning of enterprise; sole proprietors are subject to the individual income tax. A Chinese partnership is treated as a flow-through entity; that is, its income is taxable to the investors or owners. A foreign partnership, in contrast, is taxable as an enterprise under the EIT law.

According to the SAT, this rule is needed to prevent double taxation and to protect the Chinese tax base. In the case of a Chinese partnership, the assumption is that Chinese partners are taxable under the individual income tax (in the case of an individual partner) or the EIT (in the case of an enterprise partner). Treating a Chinese partnership as a conduit eliminates double taxation of the income earned through the partnership. If a foreign partnership is not taxed as an enterprise, then its income would be free from the EIT and the foreign partners would not be taxable in China.

In addition, for the first time residence is officially used as a basis for determining tax jurisdiction in the EIT Law. The term resident enterprise is defined as "an enterprise established in China or an enterprise created under foreign laws but with a place of effective management in China." An enterprise established in China refers to "an enterprise, nonprofit entity, social organization, and other type of entity that earns income and is created in accordance with Chinese laws or administrative regulations." As such, the test of residency is a combination of place of incorporation and place of effective management.

**TAXABLE INCOME**

The basic formula for computing taxable income stipulates that taxable income equals total revenue minus ex-
included income minus exempt income minus deductions minus loss carryover.

The taxable income of a nonresident conducting business in China through an establishment or site is the net of deductible costs and expenses. The taxable income of other nonresident enterprises, however, is gross income.

Taxable income earned from Chinese-source dividends, interest, rent, or royalties is the full amount received. According to the SAT, a nonresident enterprise is also liable to Chinese tax on the gross amount of fees for services provided to enterprises or individuals inside China, or for providing foreign insurance to enterprises or individuals in China. The service fees and insurance premiums are treated as Chinese-source income because the payer is in China and taxable on a gross basis.

TAX RATES

The standard rate of the EIT is 25 percent. This rate was believed to be internationally competitive. A lower rate of 20 percent applies to qualified small, low-profit enterprises. These enterprises are believed to be strategically important in creating jobs and stimulating economic growth in China, but their tax capacity is limited. To support such enterprises, a lower rate is available to them. A further lower rate of 15 percent applies to key state-supported, new, and high-tech enterprises. This reduced rate is now applicable to all qualifying enterprises, irrespective of ownership or location.

TAX DEDUCTIONS

Costs, expenses, taxes, losses, and other outlays are deductible in computing taxable income. This reflects the principle that income is a net concept. According to the SAT, for an item to be deductible, it must be truthful, or real (zhenshi xing), legal, and reasonable. The expense must have been incurred and supported by evidence. Any unlawful expenditure, even if deductible under accounting principles, cannot be deducted in computing taxable income. The reasonable test requires that the expense be “normal” and “necessary” for the purpose of earning income. For mixed business and personal expenses, a reasonable allocation must be made.

Deductible costs and expenses are generally self-explanatory. These include the cost of wages, salaries, bonuses, as well as contributions to basic mandatory retirement plans, basic medial insurance plans, basic unemployment insurance plans, workers’ compensation plans, family-planning insurance plans, housing provident funds, and other social insurance plans. Contributions to supplementary insurance plans, medical insurance plans, and other plans approved by State Council are also deductible.

Nondeductible items include dividends, taxes paid under the EIT law, late-payment penalties, fines and other penalties, sponsorships, unverified reserves, and other amounts incurred for nonincome-earning purposes.
For capital assets and inventories, generally speaking, it is the historical cost, or the laid-out cost, that is deductible. The cost of fixed assets is depreciated under a straight-line method: twenty years for buildings; ten years for aircraft, trains, marine vessels, machinery, and other production equipment; five years for other instruments, tools, furniture, and other assets used in production and business activities; four years for aircraft, trains, and marine vessels used in transportation; and three years for electronic equipment.

The period of amortization is ten years for biological assets in forestry production and three years for those used in livestock production. The cost of acquiring intangible assets—such as patents, trademarks, copyrights, land-use rights, nonpatented technologies, and goodwill—is generally amortized over not less than ten years. But the cost of purchasing goodwill, such as a customer list, is deductible when the business is sold or liquidated. (Goodwill, in this case, refers to the value of a business based on expected continued customer patronage because of its name or reputation.)

**TAX CREDITS**

A credit is a yuan-for-yuan deduction in computing tax liability. There are two types of credits recognized by the EIT law: a foreign tax credit to prevent international double taxation, and tax credits as a form of subsidies for preferred investments, such as venture capital and investment in environmental protection, energy and water conservation, and production safety.

**TAX INCENTIVES**

The EIT legislation provides tax incentives to industries and projects that are specifically supported and encouraged by the state. Tax incentives take a variety of forms, including full or partial exemption, tax rate reduction, accelerated depreciation, imputed additional deductions, and tax credits.

Tax-preferred enterprises include small, low-profit enterprises; high-tech enterprises; and nonprofit organizations. Tax-favored investments are those in agriculture and fishing, infrastructure, venture capital, environmental protection, and production safety, and investments in ethnic minority regions, which are often less developed.

High-tech enterprises receive several types of tax incentives, including a reduced tax rate of 15 percent; exemption of income from technology transfer; additional deduction for research and development expenses; accelerated depreciation; and special deductions for eligible investors of high-tech enterprises.

So-called green industries or projects sometimes qualify as high-tech enterprises. In addition, 10 percent of the income is excluded from taxable income if it is derived from products made by way of “comprehensive utilization of resources” in accordance with the standard published by the central government. In addition, 10 percent of the expenditures on purchasing qualified equipment specifically for the purpose of protecting the environment are creditable against income tax. This credit can be carried forward for five years.

**TAX CERTAINTY**

All things considered, the EIT is an improvement over earlier corporate taxes in China. Even though the tax law contains many regulations and conditions, these regulations and conditions are published as administrative rules and available to the public. The EIT regime clearly provides taxpayers with more certainty and predictability, and the new rules are far more detailed and transparent than any other tax rules in modern Chinese history.

**Further Reading**

The interrelationship between humans and nature has been strong for millennia in China. Factors such as climate, landscape, and natural resources have shaped the culture of China since the seventh century BCE. Reinforced by Confucian and Daoist philosophies, the ancient Chinese stressed the need for balance and order between humans and nature.

China is a huge country with a great variety of terrain as well as different climates; this makes it difficult to speak of a single ecology or environment in the region. Nevertheless, there are four issues relevant to the environment that a majority of ancient Chinese had to contend with, regardless of their location: water, deforestation, farming, and regional interdependence.

**Water Issues**

The area above the Yangzi (Chang) River Valley and the high mountain barriers north of Guangdong Province is considered northern China; here the climate is dry and subject to the effects of cold-air blocks from Mongolia and Siberia. The conservation of water for domestic use and irrigation was one of the most precarious tasks that individuals and communities in this region had to undertake. Summer’s torrential rains and spring’s huge flows of melted snow and ice from high mountains could create nearly instantaneous floods, sometimes lasting for very long periods of time. Fields and houses would be washed away, topsoil carried off, and thick deposits of silt left after the waters receded. No simple water-control project could manage this many difficult conditions. It is not surprising that the legend of Emperor Yu, the founder of China’s mythical first dynasty, the Xia dynasty (2100–1766 BCE), claims that Yu had channeled the overflowing waters of the Huang (Yellow) River back into their proper course. Yu’s father, according to the same legend, had previously attempted a dike-building project that failed, resulting in renewed flooding—and Yu’s father’s execution. However, this legend actually may express a collective memory of great deluges that, unlike the flood in the story of Noah, did not occur only once.

In southern China, monsoon rains regularly bring in tremendous quantities of water. Torrential rains can generate raging downpours in moments. For these reasons, Chinese farmers worried constantly about water conditions that could bring ruin to their lives. But lack of rain in the south could be just as disastrous as a flood: Rice paddies require huge amounts of water, and a short period—only a few days even—of severe drought could wipe out an entire season’s crop. Thus, water issues were just as worrisome in the south as they were in the north.

The most common way to deal with the problem of managing water for irrigation and daily use was to try first to preserve surplus rainfall by sinking wells and using small ponds. Every Chinese village in ancient days had a public well, and larger households might have their own in the backyard or kitchen. Ancient Chinese hydraulic
engineers also created marvels of technology such as the Du Jiang Dam, built in 256 BCE in western China’s Sichuan Province, which divided an entire river in two to irrigate the Chengdu basin. A water gate built from basic materials—bamboo, pebbles, and timber—could be opened and closed to adjust the water flow that irrigated several tens of thousands of hectares of land there. Amazingly, it still works today, with only minor adjustments, 2,200 years after it was built.

Chinese hydraulic engineers also built many canals to link lakes and rivers of different systems into wider networks. One canal system in Liangqu (in the present-day Guangxi Zhuang Autonomous Region, in the far south of China) joined two river systems at their origins high in the mountains. This mini-prototype of the Panama Canal had its own dam and reservoirs and an intricate system of locks to raise and lower the water level so that ships literally could move up and down mountains. As with Du Jiang Dam, this project is still in operation two thousand years later.

**Deforestation**

The Chinese used wood as a building material to construct houses as early as the Neolithic Age (7000–2000 BCE), especially in the south. The frames were wood, and mud brick and stamped earth were used to complete the walls. Since wooden materials do not last as long as stone (which why very little ancient architecture survives in China), eventually a house would need to be repaired, or replaced completely, and more timber was thus consumed. Also, the Chinese originally cooked over open fires fueled with firewood, a practice that evolved into the use of stoves. Wood-burning kilns for the production of pottery and ceramics and foundries for bronze and iron also consumed enormous amounts of wood.

In northern China, the arid and cold weather meant that new trees grew slowly on formerly forested land; this new growth had no chance of matching the speed with which trees were cut down for construction and fuel. Barren hills and fields therefore became commonplace in the
northern countryside. As early as the fourth century BCE, the great philosopher Mencius (371–289 BCE) remarked that cities all seemed to be surrounded by landscape resembling bald heads freshly washed. Soil in the north was a fine yellow powder that simply could not be conserved without vegetation, and the phenomenon of rapid desertification had been prevalent in China since very early days. Loose sand carried away by river systems eventually came to rest as heavy silt deposits that raised riverbeds higher and higher, until the dikes and banks bordering them literally lifted some of China’s northern rivers into the air. The waters of these so-called hanging rivers flowed at a higher level than the surrounding lands; the Huang (Yellow) River is the most notorious of these.

In southern China, warm and humid weather allowed cut vegetation to grow back more quickly than in the north, but still the speed with which trees were cut down was even faster. Southern hills were normally covered with dwarf trees and bushes whose shallow root systems were completely inadequate to hold the soil in place during the torrential rains of the monsoon. Firewood became so expensive that eventually the Chinese had to find creative ways of conserving fuel; they invented a fuel-efficient stove as early as the second century BCE in which a small amount of straw, hay stalks, or the stalks of crops could be burned and generate a short but intense heat. The Chinese method of stir-fry cooking was extremely fuel-efficient, as the ingredients were prepared and chopped ahead of time, and needed only minimal time on the fire to be cooked thoroughly. The stove was built in such a way that, after cooking two or three stir-fry dishes, the residue heat in the stove and ash could be used to boil water or cook rice. Indeed, the art of Chinese gourmet cooking is the direct result of a conservation-minded lifestyle.

In northern China, where animal husbandry was more common, people used dried animal dung (either in cakes or powder form) and grain husks as basic fuels for cooking and heating the home on winter days. Although these fuels burned at a lower temperature than wood, they produced a sustained heat that made the houses comfortable. While there is no literary record nor archeological evidence that indicates precise dates, heat channels under floors and beds that conducted heat from the stove throughout the home are believed to have been invented no later than the second century BCE; they became commonplace in northern China no later than the ninth century BCE. In contrast to the south, northern Chinese cuisine relies heavily on steamed breads, fried pancakes, and boiled noodle soups, all of which can be produced economically by using just a small portion of such long-lasting heat.

Farming

Chinese agriculture emerged in northern China as early as 7000 to 6000 BCE, when millet was domesticated. The main crop in the south was rice, which was cultivated at about the same time. Early on, Chinese farmers practiced slash-and-burn agriculture (which burns or fells forests to create fields for crops or livestock) to open new fields; they also knew to leave some fields unplanted to preserve the richness of already opened land. By the third or fourth century BCE, population pressures in the highly crowded central plain (around the middle reaches of the Yangzi River) led to an extremely high population density that put a great burden on what little agricultural land was available. Farmers had to use relatively small patches of land to produce enough food to feed a large population, and as noted above, environmental conditions already were not favorable. Under such challenging conditions, Chinese farmers developed practices that were highly labor-intensive. Chinese farming required an enormous amount of human labor to produce food, and it had to draw upon extra labor during the busy harvest seasons. Farmers had to develop labor-consuming field management in order to utilize the soil, and the population, to their maximum capacities. The soil needed more workers, and the working population thus needed an increasing supply of food. It was a vicious circle.

To maximize the use of limited resources, Chinese farmers carefully calculated their timing in order to catch all available moisture when the winter snows melted, and they would cover the snow with mats in order to prevent it—and the water it would provide in the spring—from being blown away. They found various methods of shortening the growing seasons, such as interpolating crops. This planting of different crops alternately on a plot of land meant that nutrients that had been removed from the soil by one crop could be replenished by the one planted subsequently, thereby conserving the soil’s fertility. Rice farmers also used concentrated fields as nurseries, growing densely-planted sprouts in a very small

© 2009 by Berkshire Publishing Group LLC
area while another crop reached maturity in the larger fields; after the mature crop was harvested, the partially grown sprouts could be painstakingly transplanted into the larger field. Beginning in the second century CE, the size of China’s population meant that the country could no longer afford to leave more than a very few fields fallow. Most were in constant use for food production, and their soils came to depend entirely on fertilizers, as the original topsoil was completely exhausted. For fertilizers, they used burned ash, silt dredged from the bottoms of ponds, crumbled earthen walls, and the excrement of animals and humans. The skills necessary to use the intensely crowded land area most effectively eventually spread throughout China, even finding their way into neighboring countries.

This need for intensive cultivation also meant that there was little or no open pasture in which domestic animals could graze. The Chinese countryside was dotted with pigs and chickens, however these animals did not run wild. Rather, they were kept in enclosed yards or cages, and their waste was collected for use as fertilizer. Fish grew in hatcheries surrounded by fruit trees and other plants. Ducks were kept in ponds. The silt that collected at the bottom could be dredged up periodically and used to fertilize the fields. Thus a small, nearly independent ecosystem could develop around a pond next to a village.

Regional Interdependence

These local farming ecosystems were not completely independent of each other; they were part of a much larger system that brought together regional labor, land, and crops into an exchange network that constantly sought the most economic and efficient way to utilize local conditions and resources to produce essential goods. These products were not made for subsistence (that is, for personal use), but rather for trade, and might include staple goods, preserved or cooked foods, clothing, furniture, utensils, or tools. They were gathered by itinerant merchants to be sold in other areas. A network of hierarchically arranged market centers based in towns and cities spread throughout China and siphoned local products from rural areas, redistributing them elsewhere. Even when China suffered the chaos of internal division and civil war, the interregional economy was so tightly integrated that political divisions could not stop the exchange of goods and wealth.

A sustained and ongoing process of debate in which several schools of philosophy, most notably Confucianism and Daoism, eventually shaped the Chinese way of thinking took place during the sixth century BCE in China. In the emergent Chinese worldview, the cosmic order, the natural world, human society, and human individuals were all integrated into a comprehensive system in which energy and resources constantly circulated. The parts are inseparable from the whole. Consider, for example, the term mai, which means the veins and arteries of the human body; the very same term is also used to denote a river’s course, mountain ranges, a network of human relationships, a family’s lines of descent, or even a system of highways. The constant and unimpeded flow and circulation of energy, or Qi, through such systems—in the sky as atmosphere, in a person as spirit—is the very definition of vitality. Without a proper circulation of Qi, there is death. Chinese acupuncturists use the term xue, which signifies an important point of connection in which the human body’s circulating Qi gathers and disseminates; the same term xue is also applied in feng shui (Chinese geomancy) to describe a favorable site on which to construct a city, a house, or a grave.

The Chinese mentality, as reflected in the Confucian and Daoist philosophies, strives to achieve and maintain a balance between the order of the cosmos and nature on the one hand, and the order of human society on the other. Human effort should not be used for the conquest or exploitation of nature, but rather it should blend as much as possible with the movements of natural forces. Therefore, the ancient Chinese formed in their minds an interactive network between and among the cosmos, nature, human society, and the human individual; these various levels are understood to be interconnected and constantly engaging with one another in a carefully maintained dynamic equilibrium. To upset any part of the balance is to tempt adverse repercussions throughout the entire system. Hence, the Chinese believe that the misuse of nature by humans will return in the form of nature’s retaliation. In the same mode, the Confucian motto of forbearance states: “Do not do unto others what you do not wish them to do to you.” For the Chinese, the system of interrelations and balances includes the small ecosystem around a pond, the larger farmstead and its natural surroundings, and the enormous marketing network for the exchange of resources. shui, literally translated, means “wind and water.” The terminology is quite telling, in that it reveals the fundamental belief that human life is heavily influenced by the blowing winds and the flow of the waters.

Cho-yun Hsu
By the early twentieth century, China’s population growth had placed great demands on natural resources. Increasing industrialization and modern technology continued the devastation and caused many types of environmental pollution. China’s awareness of the need to curb pollution came about initially in the 1970s; in the twenty-first century China still struggles with balancing environmental concerns and economic progress.

Under the rule of the Qing dynasty (1644–1912) the Chinese empire more than doubled the size of its territory, and its geographical and cultural diversity were greater than those of any other country. In the rural northern and western regions peopled by ethnic minorities, yaks filled the stables of Buddhist monasteries on the plateau of Tibet, horses and deer roamed the plains and forests of Manchuria, camels passed through the inner Asian desert oases in Xinjiang, and goats grazed the pastures of Mongolia. In the southwestern and southern regions native peoples had fought losing battles against the invasions of Han Chinese colonists, miners, traders, and soldiers who came to exploit the riches of the tropical rain forests, timber, mineral resources (including copper, iron, tin), and eventually their farming soils. In the fertile river valleys and plains in the eastern half of China, the Han Chinese population had grown from about 150 million in 1700 to maybe 350 million in 1800 and to 450 million in 1900, creating an enormous need for resources including metals, timber, cotton, wool, fuel, pork, and many other products. Spurred on by the new American crops (such as maize, potatoes, and tobacco) and a growing demand for tea, many farmers relocated to take advantage of the hills and mountains of central and southern China, and millions even went overseas. Wherever people moved, the demand on natural resources increased. But economic growth was uneven, and so were its environmental effects on different regions.

A Landscape Made by the Human Hand

After the eighteenth century forests were cut down with increasing speed and the land was reclaimed for agriculture. Farmers and other settlers ruthlessly misused the shrinking natural vegetation and other resources of the hills and upstream areas. Many mountain soils, unable to sustain a long period of farming, rapidly eroded and became too thin and stony for raising crops. On gentler slopes and along river valleys, terraces were built to conserve water, soil, and nutritional elements. Lakes and low-lying land in river floodplains were restored for irrigated agriculture. These resulting anthropogenic (or human-created) soils became stable and gave high yields of rice. Thus much of China’s landscape was created by the human hand. But land and people became vulnerable to floods and droughts as riverbeds were raised and flood retention capacities and natural vegetation were reduced. Along the coast, the silt-laden rivers deposited much sediment, and
land was reclaimed from the sea on a large scale, not only at the mouth of the Huang (Yellow) River, but also near those of the Yangzi (Chang) and other rivers.

**Dry and Irrigated Farming: North and South**

Water is in short supply in northern China but ample in southern China, where the monsoon climate brings an uneven distribution of rainfall, with spring droughts and summer floods. Some land along the rivers of northern China and near mountains was irrigated by surface water, but most farming was dry. Shallow wells supplied water for agriculture and drinking. Wheat, millet, sorghum, and maize were dominant crops; as a result diets were poor and particularly lacking in animal protein. Constrained by poverty and difficult transport, few farmers could afford to grow cash crops such as cotton, tobacco, and peanuts, or to keep pigs for manure and pork. In contrast, in the Yangzi River basin in central and southern China, water was abundant and, where necessary, was caught in tanks and reservoirs in the hills and subsequently stored in paddy fields. Rice yields were high, transport was convenient, and income was supplemented by sericulture (silk production), tea growing, weaving, and other industries. With these advantages, population was dense, crowding the cities, market towns, and villages that stretched along rivers, roads, and canals.

**New Factors of Change**

During the final years of the Manchu dynasty, four new elements began to change China’s traditional environment.

First was modern transport. Government concessions were given to build railroads; as Chinese and foreign railway companies began to develop land and to exploit mines and forests, new cities sprang up. Because of improved railway transport, millions of colonists moved into Manchuria and other outlying regions. Famines were much reduced; great droughts in northern China (1876–1878) and in northwestern China (1899–1900 and 1929–1930) had cost millions of lives, but in 1922 the North China Plain was saved by its railroads. By the 1930s China had over 20,000 kilometers of railways. Modern tar roads and rubber-tired carts and trucks greatly reduced short-distance transport.
cost. Old city walls were torn down to make way for new development. Nevertheless, political strife between war-lords continued to tear China apart. Other than areas that supported mining, modern development remained concentrated in the coastal areas, particularly in Taiwan, Japanese-controlled Manchuria, and a few cities.

Second, after 1870 modern mining and other industries developed, such as the Pingyuan coal mines near Beijing, the Hanye iron works in Hubei, the Shuikoushan lead mines in Hunan, and the Dongchuan copper mines in Yunnan. Traditionally, mines and kilns for porcelain and bricks had used much wood fuel from their immediate surroundings, but the new large-scale mines needed even more and soon were served by railways, which imported additional supplies from other areas. After 1895 foreign industries were introduced into the western treaty ports. Under foreign protection, Shanghai, Tianjin, Guangzhou (Canton), and other cities rapidly developed into industrial and commercial centers. The 1931 industrial survey reported 3,800 modern factories located primarily in urban areas. New wide-ranging technologies were adopted in textiles, coal mining, iron melting, oil pressing, and flour milling. New products were introduced, and electricity and machinery changed people’s lives. The urban population expanded rapidly, leading to crowded housing, crime, and unsanitary conditions. Even so, city life was more secure than life in the countryside. But the political crisis between the Communists and the Nationalists (Guomindang) and the Japanese invasion of the 1930s, World War II, and the subsequent civil war retarded China’s modern industrial development; in 1949 only some coastal cities and Manchuria had modern industry.

Third, new crops, animal breeds, and cultivation techniques were brought into China by Chinese entrepreneurs living overseas, Western missionaries, and agricultural scientists. American cotton, Italian wheat, British pigs, Swiss goats, and Russian and Dutch dairy cattle gave higher returns than most local varieties; eventually many local varieties disappeared, although some qualities were maintained in crossbreeds. Chinese cotton growers and soybean growers began to produce for the Japanese market and native factories. Through increasing commercialization, the standard of living improved slightly in most regions, including rural areas.

Fourth, China’s government became more economically exploitative and socially invasive. Traditional property regimes (or the consistent, stable pattern of their management) were replaced by new legal arrangements that allowed fuller exploitation of land and other natural resources. For instance, traditional Mongolian land rights were revoked and sold to Japanese, Russian, and Chinese chartered companies. Improved communications, modern arms, and new bureaucracies strengthened the reach of the State. Nationalism and other ideologies demanded that China should be strong and its people lifted from poverty. Rising expectations led to revolutionary movements and civil wars, in which warring parties mobilized available natural and human resources on an unprecedented scale.

Rural Misery

In spite of such efforts to modernize China, its image as a country plagued by bandits, soldiers, opium, and natural disasters remained valid. The 1931 and 1935 floods of the Yangzi River and the deliberate dike breaks in Shandong to force the Huang River into a southern course in 1938 destroyed millions of people, cattle, and homes. The Japanese invasion and atrocities such as the mass murders in Nanjing made millions flee to the interior, from where the Nationalist government continued its struggle. Stark poverty, high infant and child mortality, and many epidemic diseases were constant. About 1 million Chinese, mostly urban young adults working indoors, died of tuberculosis every year; cholera and malaria were common. Most farmers, working barefoot in the fields, spreading human excrement over their vegetables, living with their pigs, and drinking unsanitary water, were infested with parasites, affected by viruses, and often died before the age of sixty. Few families managed to attain the Confucian ideal of three generations living under one roof.

Loss of Forests and Vegetation Cover

By 1800 most of China’s original forests had already been cut down; some remained in the northeast and southwest. China’s forest cover decreased more rapidly because railroads made commercial exploitation feasible and also because land was reclaimed for agricultural use. By 1940
Manchuria’s forest cover and timber stocks had been halved, and by 1985 they were halved again. By 1962, in the upper basin of the Yangzi River, forest cover shrank from 50 percent to less than 20 percent, and in Sichuan it decreased from 34 percent to 12 percent. In particular the Great Leap Forward (1958–1961, an unsuccessful attempt to decentralize the economy by establishing a nationwide system of people’s communes) has been blamed for extensive felling of forests to acquire building material and fuel for new rural industries, most of which was wanton. Commercial logging, agricultural land reclamation, household fuel use, and desiccation all had great impact on China’s environment, and the consequent changes in river activity caused greater vulnerability to floods and droughts.

Under Communism’s establishment of nationwide communes during the Great Leap Forward, afforestation campaigns were organized on a massive scale. Villages were obliged to plant a hundred trees per inhabitant to provide fuel and to combat erosion, mostly along roads but also on waste hills. Often done without sustained follow-up, tree planting failed more often than it succeeded. For instance, along the northern deserts where pastures had been restored to create farmland, a giant shelterbelt (a barrier of planted trees and shrubs) was created to reduce wind velocity and protect the new farmland against desertification—an almost futile effort. Planting tea or fruit trees on wasteland did not always help against erosion either. The forest area grew to 125 million hectares in 1988 and to 160 million hectares in 2004, but most forests today are young and the timber of poor quality. In 1988 the government raised the price of timber, severely restricting its use for building purposes and railway sleepers, and began importing pulp and paper. Reserving land for forest growth (by now 1 million square kilometers)

Terraced wheat fields in China. Over the centuries, forests have been cut down to make way for arable land, but the deforestation has led to soil erosion and flooding. PHOTO BY JOAN LEBOLD COHEN.
and selling long-term land leases of local forests, pastures, and wasteland to individual farmers have been adopted as solutions for collective squandering of resources and failing common property regimes, but with mixed success. China’s timber stock seems to be rising again, and some erosion-prone farmland in the hills has been taken out of cultivation. But global warming has intensified droughts in the north and floods in the south.

### Population and Birth Control Measures

China’s population increased from 583 million in 1953 (the first census) to 1 billion in 1982 and more slowly to 1.2 billion in 2000. According to the World Factbook, natural growth is down to 0.6 percent per year now. Remarkably, as the Chinese people became more affluent and resource constraints lessened, birth control policies became stricter. In 1958 new household registration rules were adopted that required rural migrants to metropolitan areas to have urban work or school permits or settlement permits from authorities; this started the formal separation of rural and urban households. Strict urban rationing of food, cloth, and housing and strict controls on population movement succeeded in reducing the flow from rural to urban areas. Consequently, urbanization rates remained low, and the rural population increase had to be accommodated within each village, regardless of the availability of land and other economic resources. The Communist regime made great efforts in health care and education. Vaccination programs put an end to most childhood diseases, and primary school enrollment increased from 50 percent in 1952 to 85 percent in 1965 and became almost universal after 1975. Life expectancy at birth increased dramatically after the early 1960s, also because of improved diets and medical care, and during the 1990s it continued to rise (although more slowly) by another two years to 69.1 for men and 73.5 for women, which is close to levels in the industrialized world.

Many factors contributed to China’s fertility decline during the period from 1950 to 1990. Total Fertility Rates (TFR) dropped from 5.8 in the late 1960s to less than 3 by 1980 and below replacement value (or the number of children each woman must bear to maintain current population levels) in the 1990s (TFR is always measured per woman over her entire life time). Women’s liberation, education, full female employment in rural collectives and cities, cramped urban housing, decreases in child mortality, and greater availability and knowledge of contraceptive methods were contributing factors to the decline. But the presence of severe state measures, with heavy penalties and collective pressure and different policies for urban and rural areas, was also an influence. Politicians
were and still are prompted by Malthusian (relating to the theories of English economist Thomas Malthus) concerns about limited natural resources and food supply. During the 1980s scientists calculated an “optimal” population of 700–800 million people. Chinese government at all levels feared the social burden of having more children. State family-planning policies started in 1971 with the slogan “late, sparse, and few,” meaning late marriages and only two children per couple. The rule of only one child was instituted for the urban population and state employees in 1978 and later spread to suburban and affluent rural areas. A “one-child certificate,” a contract that rewarded complying mothers but carried severe penalties for offenders, upheld the rule.

In many rural areas a second child is allowed only if the first is a girl. Consequently, after ultrasound scans became widely available, the incidence of sex-selective abortion escalated. The birth ratio of boys to girls for second children rose from 1.2 in 1990 to over 1.5 in 2000. Popular acceptance of the one-child policy has increased in urban areas but not in rural areas. The 2001 family-planning law severely restricts citizens’ reproductive rights while extending legal protection and quality health services to mothers and infants who abide by the law. Its prohibition against using coercion to enforce birth control is mainly cosmetic because the law gives local governments unlimited powers to impose severe sanctions on offenders, upheld the rule.

Effects of Socialist Planning in Agriculture and Industry

Central socialist planning is known for its great successes and even greater failures. Communist leader Mao Zedong’s megalomaniacal Great Leap Forward was different in that it combined central targets and directives with local autocracy and mass campaigns, but the results were still disastrous. In 1958 large communes organized farming along military style and started a mass campaign to produce iron in 600,000 small “backyard” furnaces. Urban population increased from 90 million in 1957 to 130 million in 1960. The cities could not accommodate this influx, and food shortages followed. The idea to open up new land, terrace hills, and build reservoirs everywhere proved counterproductive and environmentally destructive. Distribution networks broke down, grain output dropped, and the resulting famine cost 25 million lives during 1960 and 1961. There were long-lasting effects on natural resources; for instance, the decimated fish population of China’s largest lake, Qinghai, still has not recovered. It also created an obsession with local self-reliance in food grain.

The large fields created under collective farming, although more efficient in the use of oxen, machinery, irrigation, fertilizers, and pesticides, were more vulnerable to erosion and salt saturation, or salinization. Since 1958 about 35 million hectares (one-third of China’s farm acreage) have been lost or diverted to other uses. Twice as much was reclaimed for agriculture, but much of it was poor soil in remote areas or on steep hill slopes. Chinese colonists were settled in border regions, from the Sanjiang marshes in the extreme north to the tropical forests of Hainan and the deserts of Xinjiang. Their irrigated agriculture destroyed the pastures and livelihood of native people. By the 1970s land reclamation, overgrazing, and reduced precipitation—another consequence of deforestation—had turned a half-million square kilometers of northern prairies into deserts and reduced grasslands by one-third to one-half on the remaining prairies. One-sixth of China suffered from serious soil erosion. One-quarter of China’s reservoir capacity had silted up, and natural lakes such as Dongtinghu had lost most of their flood-retention capacity. During the 1990s, on average, 5–15 million hectares were seriously stricken by flood every year, and 5–20 million hectares were affected by drought. Nevertheless, continuous increases in grain yield since the late 1960s were achieved with improved varieties, expanded irrigation, liberal applications of chemical fertilizers, and the use of electric pumps. Recently China has promoted bioengineering, and now half of its cotton and much of its soybeans and maize have been genetically modified to increase pest resistance.

Fearing foreign invasion, China set up many heavy industries in remote mountain areas after 1965. In socialism,
although big was beautiful, all provinces and cities had to, or tried to, become self-reliant. Socialist planning invited local governments and factories to maximize output and distribute according to plan, regardless of efficiency or cost. Resources such as land, water, and ores had no value in their own right; only product and output were important. This led to wasteful use of energy, hoarding of raw materials, and blind production. Moreover, China was isolated, and without access to foreign technology most industries continued to copy or adapt the outdated Soviet technology of the 1950s. When China finally woke up to the demands of the market in the 1980s, it found poor locations had been chosen for large parts of its industrial apparatus, and that almost all were antiquated. Thus traditional industries could not compete with the new industries established with foreign technology (and increasingly with foreign capital) in the coastal regions.

As direct state involvement in the economy declined, the central government concentrated on planning and implementing large projects. In spite of government efforts to restrict urban inflow, increasing differentials in development and income made tens of millions of poor farmers migrate to nearby cities or to eastern China. Average rural income in poor provinces was only one-tenth (or less) of that in large cities such as Shanghai and Guangzhou. Although government subsidization of antipoverty programs in rural villages was effective in providing a minimal sustenance of life, primary education, and health care, the rural population still depended entirely on the collective provisions of its own villages and was not entitled to any urban employment or social security. However, as agriculture became less and less rewarding, more was needed. At the end of the 1990s the government tried to redirect the rural outflow toward rural towns and to create employment there instead. Urbanization is now accepted as inevitable and even positive for socioeconomic development. More recent political priorities are urban housing, drinking water, sanitation, and improved indoor air quality with a transition from coal to gas use.

A monumental plan to “develop the west” (The Great West Development Plan) is attempting to expand the physical and social infrastructure of twelve western provinces and integrate them into China’s economy; the government hopes to have the west fully caught up with the east by 2050. New railroads, highways, mines, and factories will lead to fuller utilization of the resources of western China. Coal-fired power plants send their electricity to the east, pipelines began transporting gas and oil from Xinjiang to Shanghai in 2004, and a railway from Lhasa to Qinghai finally connected Tibet with China in 2006. Reducing the negative environmental consequences of forced rapid development will be a great challenge to local governments. The giant Sanxia (Three Gorges) hydroelectric station on the Yangzi River is nearing completion, and, over 1 million people must be relocated from its reservoir. Original plans for resettlement of farmers in upland areas have been modified after the 1998 Yangzi River flood disaster alerted authorities to the dangers of water and soil erosion because of farming the hills. Another grand scheme transfers water from the Yangzi River basin to dry northern China; this is a cherished dream but it poses enormous problems. So far pumping water north through the Grand Canal has proven rather costly. In 2000 engineering work started on a middle route to transport water from the Hanshui River at Danjiangkou to Henan and across the Huang River.

**Industrial Pollution and Remedial Measures**

In 1972 pollution accidents affected Beijing’s fish supply from the Guanting Reservoir and the shellfish from Dalian Bay. The government disclosed that mercury and other heavy metals dumped into the Sungari and Nenni rivers were poisoning both fish and people. Such an admission reflected a beginning awareness of the need to check pollution and prepared China for participation in the 1972 United Nations conference on the environment and adoption of its first environmental regulations. A 1977 survey of sea pollution found high industrial discharges of heavy metals and serious oil spills; 15,000 square kilometers of oil covered the Bo Hai (an arm of the Yellow Sea), a traditional source of shrimp and fish for the banquets of China’s politicians and administrators.

Early corrective policies focused on management of river systems, waste-release standards for new or expanding large industries, cleanup of major cities, reduction in pesticide use, food safety inspection, and research and monitoring. After 1979 industrial expansion plans were screened for their discharge standards; regulators first focused on the metallurgy, oil, textile, paper, food, building
materials, and machinery industries. However, compliance was uneven and depended on the development level and financial resources of the responsible local government.

A trial environmental law was passed in 1979. It focused on prevention, along with the principle of “the polluter pays.” Surface water-quality standards were introduced in 1983 and 1986, and local governments were made responsible for monitoring water quality and preventing further degradation. Three standards of ambient air quality were set for different types of areas, and polluting businesses were charged for emissions above the acceptable level. Laws for conservation of forests, grasslands, fisheries, and wild animals were passed during the mid-1980s, and by 2000 over twelve hundred nature reserves occupied 10 percent of China’s territory, one-half of which were in Tibet and Xinjiang. Environmental laws were introduced for the marine environment (1982), water pollution (1984), air pollution (1987), solid waste (1995), and noise (1996). Environmental impact assessments were required for a growing number of construction projects. In 2000 a total emission-control permit system was introduced for certain areas, whereby emission quotas are distributed or traded.

The 1980s were a period of rapid, visible, and cost-effective early advances in pollution prevention and treatment efforts. From 1982 to 1984 the State Council ruled that 6 or 7 percent of investments in capital construction and renovation projects should go to pollution prevention and treatment. Environmental protection became a standard part of the government’s five-year plans. By 1987, 0.8 percent of the gross domestic product (GDP) was spent on environmental protection, and its proponents demanded that this eventually should rise to 1.5 to 2 percent. But subsequently this percentage fell, and only at the end of the 1990s did it increase to a level of around 1 percent. In 2003, the State Council pledged to invest 1.35 percent of China’s GDP in environmental protection from 2006 to 2010.

**Weak Enforcement of Rules**
